SCIENCE

NEW SERIES. VOLUME XXXIX

JANUARY-JUNE, 1914

NEW YORK
THE SCIENCE PRESS
1914

229904

THE NEW ERA PRINTING COMPANY,
41 NORTH QUEEN STREET,
LANCASTER, PA.

CONTENTS AND INDEX.

NEW SERIES. VOL. XXXIX.—JANUARY TO JUNE, 1914.

The Names of Contributors are Printed in Small Capitals.

- ABBOT, C. G., Solar Constant of Radiation, 335
 ADAMS, C. C., Animal Ecology, V. F. SHELFORD, 580
 AERIALS, Small, C. W. WAGGONER, 463
 AEROLGY, Standard Units in, A. McADIE, 391
 AGRICULTURAL CHEMISTS, Assoc. of Official, Presidential Address, 9
 AGRICULTURE, Chemistry of, G. S. FRAPS, 9
 AIKINS, H. A., Government of Societies, 711
 ALFALFA, P. J. O'GARA, 905
 ALLEN, I. C., Amer. Petroleum Soc., 585
 AMAZON, Expedition to, F. S. DELLENBAUGH, 68
 AMERICAN ASSOC. for the Advancement of Science, Address of President, 1; Atlanta Meeting, 39; Section B, 42, 697, 881; Section K, 51, 794; Section A, 113; Section L, 154; Local Branches, 246; Section E, 263, 398; Section G, 299, 405; Report of Secretary for South, 350; Pacific Coast Committee, 352; Section C, 364; Section F, 364; Section H, 546; Meeting of the Council, 640; Committee of One Hundred on Scientific Research, 680; Financial Statement, 694; San Francisco Meeting, 781
 ANDREWS, R. C., Sea Elephant, 656
 ANTHROPOLOGICAL SOC., of Wash., D. FOLKMAR, 146, 622, 919; Amer., and Amer. Folk-lore Soc., G. G. MACCURDY, 296
 APES, Anthropoid, H. GIFFORD, 872
 APPOINTMENT and Tenure, E. D. SANDERSON, 890
 ARCHIBALD, R. C., Winslow Upton, 202
 ARMSBY, H. P., S. W. JOHNSON, 509
 ARNOLD, R., and H. HANNIBAL, California Eocene, 906
 ASTRONOMICAL and Astrophys. Soc. of Amer., P. FOX, 333
 ATLANTIC OCEAN, H. C. JONES, 726
 ATOMIC WEIGHT of Lead, 831
 AYER, J., Amer. Soc. for Pharmacol. and Exper. Therapeutics, 144
 BACON, R. F., Robert Kennedy Duncan, 498
 BACTERIAL TYPES, C.-E. A. WINSLOW, 77
 BACTERIOLOGISTS, Soc. of Amer., Presidential Address, 77; A. P. HITCHENS, 763, 789
 BAEKELAND, L. H., Morris Loeb, 537
 BAILEY, S. I., Astronomy, H. Jacoby, 27
 BANCROFT, W. D., Chemistry, W. A. TILDEN, 789
 BASSLER, R. S., Paleontology, Soc., 187
 BAYLEY, W. S., Crystallography, G. LINCK, 288
 BECHTEREW, W. von, Psychology, H. C. WARREN, 426
 BEDELL, F., Alternating Currents, D. C. and J. P. JACKSON, 106
 BEETLES becoming Parasites, V. L. KELLOGG, 360
 BEINHART, E. J., and H. K. HAYES, Mutation in Tobacco, 34, 284
 BERRY, E. W., Fossil Plants in Canal Zone, 357
 BESSEY, C. E., Botanical Notes, 72, 329, 790, 946; Trees of H. L., J. F. Rock, 213; Botany, J. M. Coulter, 358; Rocky Mountain Flowers, F. E. and E. S. CLEMENTS, 909
 BILLINGS, J. S., Portrait, B. G. WILDER, 210
 BINGHAM, H., Peruvian Expedition, 679
 BIOLOGICAL, Soc. of Wash., D. E. LANTZ, 187, 660; W. L. MCATEE, 844; Chemists, Amer. Soc., P. A. SHAFFER, 218; Teaching, M. F. GUYER, 371; M. A. CHRYSLER, 377; Station, Fairport, R. E. COKER, 457; Station Work at Univ. of Wis., 601
 BIOLOGY, Exp., Federation of Amer. Societies, A. J. CARLSON, 217
 BISON SOC., Amer., W. P. WHARTON, 586
 BLAKESLEE, A. F., and A. F. SCHULZE, Mutant in Bellwort, 621
 BLUEMEL, C. S., Stammering, S. SMITH, 469
 BORING, A. M., and R. PEARL, Plumage Patterns, 143
 BOSE, J. C., Irritability of Plants, B. E. LIVINGSTON, 511
 BOSS, B., Seth Carlo Chandler, 348
 BOTANICAL, Notes, C. E. BESSEY, 72, 329, 790, 946; Soc. of Wash., P. L. RICKER, 109, 406, 695, 919; Address of President, 733; Soc. of Amer., G. T. MOORE, 253, 289; Congress, 320
 BOTANIST, Social Obligations of, W. W. STOCKBERGER, 733
 BOTANY, Amer. Jour. of, 570
 BOWIE, W., Isostasy, 697
 BOWMAN, I., Assoc. of Amer. Geographers, 478
 BRAGA, E., Language of the Brazilian People, 535
 BRANNER, J. C., S. America, H. Savage-Landor, 577
 BRAZILIAN PEOPLE, Language of, E. BRAGA, 535
 BRITISH ASSOC. in Australia, 854
 BROOKS, C. F., Notes on Meteorology and Climatology, 31, 429
 BROWN, E. E., Education at Washington, 239
 BROWN, F. C., Scholarship in America, 587
 BRYANT WALKER EXPEDITION, A. G. RUTHVEN, 277
 BUELL, I. M., J. J. RIVERS, 319
 BURGESS, A. F., Amer. Assoc. Econom. Entomol., 220
 BURLINGAME, L., Labelling Slides, 250
 CAJORI, F., New Marking System, 874
 CARDS as Psychological Apparatus, L. W. KLINE and C. E. KELLOGG, 657
 CARLETON, M. A., Tamarisk for Dry Lands, 692
 CARLSON, A. J., Amer. Physiol. Soc., 183; Federation of Amer. Societies for Exp. Biol., 217
 CARMICHAEL, R. D., Human Progress, 883
 CARMICHAEL, R. D., Relativity, E. B. WILSON, 251
 CARNEGIE, Foundation, 780, 847; Institution, R. S. WOODWARD, 225
 CATERIDGES Ohioensis, N. A. WOOD, 759
 CASTLE, W. E., Mutation in Tobacco, 140; Multiple Factors in Heredity, 686; Natural Selection, J. C. NOTTRAM, 944
 CATTELL, J. MCK., Science, Education and Democracy, 154; Democracy in University Administration, 491
 CELL PERMEABILITY, E. N. HARVEY, 947

- Chamberlain, Alexander Francis, C. W., 821
 Chambers, E. T. D., Fisheries of Quebec, J. M. CLARKE, 428
 Chandler, Seth Carlo, B. BOSS, 348
 Chemical Soc. Amer., 387, 950
 Chemistry, Applied, Int. Cong. of, 898
 CHILD, C. M., Susceptibility Gradients, 73
 China, National Monuments of, 863
 Chromosomes, Accessory, of Man, M. F. GUYER, 721, 941; of White Man and Negro, T. H. MORGAN, 827
 CHRYSLER, M. A., Biological Teaching, 377
 CLARKE, G. A., Fur Seal Investigation, 871
 CLARKE, F. W., Columbium versus Niobium, 139
 CLARKE, J. M., Indian Ladder Reservation, 418; Fisheries of Quebec, E. T. D. CHAMBERS, 428; Eastman-Zittel Paleontology, 723
 Clarke, J. M., Devonian Fossils, C. K. SWARTZ, 393
 Clements, F. E., and E. S., Rocky Mountain Flow-ers, C. E. BESSEY, 909
 Climatic Changes, 180
 Coal Mines, Accidents in, 59
 COCKERELL, T. D. A., Science from an Easy Chair, R. Lankester, 214; The Evil Eye, R. Park, 359
 COCKS, R. S., New Orleans Acad. of Sci., 406, 514, 624
 COKER, R. E., Fairport Biological Station, 457
 COLE, A. D., Amer. Physical Soc., 370, 569, 796
 COLE, F. N., Amer. Math. Soc., 396, 442, 769
 Color, Human Skin, F. RAMALEY, 533
 Columbium versus Niobium, F. W. CLARKE, 139
 Coulter, J. M., Botany, C. E. BESSEY, 358
 Crab, Molting of, S. HECHT, 108
 CREW, H., Physical Optics, R. W. Wood, 25; Phys-ics, K. E. GUTHE, 465
 Curriculum Making, E. P. LYON, 661
 Czapek, F., Plant Chemistry, E. KREMER, 612
 DADOURIAN, H. M., Analytical Mechanics, E. W. RETTGER, 507
 Dadourian, H. M., Mechanics, E. W. RETTGER, 140, 940
 DALL, W. H., Mollusca, B. B. Woodward, 910
 DANFORTH, C. H., St. Louis Acad. of Sci., 882
 Danielson, F. H., and C. B. Davenport, The Hill Folk, A. C. ROGERS, 616
 DAUGHERTY, R. L., Water, W. McCulloh, 142
 Davenport, C. B., Rejoinder to, D. HERON, 24; and F. H. DANIELSON, The Hill Folk, A. C. ROGERS, 616
 DAVIS, B. M., Amer. Soc. Naturalists, 322, 397; Gruppenweise Artbildung, H. De Vries, 649
 DAY, A. L., Nat. Acad. of Sci., 567
 DELLENBAUGH, F. S., Expedition to Amazon, 68
 DENNIS, L. M., Gas Analysis, A. H. GILL, 286
 DENSMORE, F., Chippewa Music, A. C. FLETCHER, 393
 De Vries, H., Gruppenweise Artbildung, B. M. DAVIS, 649
 Diadophis punctata, H. H. T. JACKSON, 534
 DICKSON, L. E., Critique of an Old Review, 22
 Discussion and Correspondence, 22, 64, 99, 139, 173, 208, 250, 284, 326, 357, 391, 423, 463, 507, 533, 575, 607, 645, 686, 721, 759, 785, 827, 870, 902, 940
 Doctor's Dream, V. C. VAUGHAN, 149
 Drosophila, Fourth Chromosome, H. J. MULLER, 906
 DUNCAN, R. K., Industrial Fellowships, 672
 Duncan, Robert Kennedy, R. F. BACON, 498
 DYAR, H. G., Lepidoptera Phakæna, G. F. Hamp-son, 691
 Earth's Elastic Properties, H. G. GALE, 927
 Eastman-Zittel Paleontology, J. M. CLARKE, 723
 Education, at Washington, E. E. BROWN, 239; Pre-medical, P. G. WOOLLEY, 743; Board, 822
 ELLIOT, D. G., The Primates, G. S. MILLER, 28
 Embryonic Nervous System, O. GLASER, 730
 Entomological, Soc. of Wash., L. G. HOXTON, 224; Soc. of Amer., A. D. MACGILLIVRAY, 441; Serv-ice, Canadian, 570
 Entomologists, Amer. Assoc. Econom., A. F. BURGESS, 220
 Environment, L. J. HENDERSON, 524
 Eocene, of California, R. ARNOLD and H. HANNI-BAL, 906
 Ephemeris, and Nautical Almanac, J. A. HOOGE-WERFF, 945
 Eskers, Cause of, J. MILLIS, 208
 EVANS, H. M. and W. SCHULEMANN, Vital Stains, 443
 EVANS, P. N., Grades, 357
 Evolutionary Control, L. B. WALTON, 479
 Expert, The Day of the, B. I. GILMAN, 771
 FARRINGTON, O. C., Precious Stones, G. F. Kunz, 539
 FESSENDEN, R. A., Gyroscopic Quanta, 533
 Financial Status of College Teachers, 847
 Findlay, A., Osmotic Pressure, L. KAHLBERG, 252
 Finlay, G. I., Igneous Rocks, J. P. IDINGS, 467
 FISCHER, W. J., Matter and Memory, 209
 FLETCHER, A. C., Chippewa Music, F. DENSMORE, 393
 FOLKMAR, D., Anthropol. Soc. of Wash., 146, 223, 622, 919
 Foreign Students in America, 717
 FOITSYTH, A. R., Geometry, F. KASNER, 175
 Fossil Plants in Canal Zone, E. W. BERRY, 357
 Fourier's Series, E. B. VAN VLECK, 113
 FOX, P., Astron. and Astrophys. Soc. of Amer., 333
 FRAFS, G. S., Chemistry of Agriculture, 9
 Free Speech and the Faculty, 68
 Freedom, and Fees, 69; of Teaching, 164
 Frog, Tissues of, S. J. HOLMES, 107
 Fur-seals, 529; G. A. CLARK, 871
 Fürth, O. v., Chemistry, L. B. MENDEL, 103
 G., H. N., Arthur Henry Pierce, 456

SCIENCE

NEW SERIES
VOL. XXXIX. No. 992

FRIDAY, JANUARY 2, 1914

SINGLE COPIES, 15 CTS.
ANNUAL SUBSCRIPTION, \$5.00

American Illustrated Dictionary

These are samples of the hundreds of new words defined ONLY
in the American Illustrated

SEROLOGY

Abderhalden's reaction	Deutschmann's serum	hypnotoxin	Perutz's reaction
actinocongestin	endo-oxidase	leukoprophylaxis	quanti-Pirquet
antihormone	festness	luetin	reaction
auto-activation	Fuld's test	meningobacterin	Salomon-Saxl
Bass-Watkin's test	hapt-agglutinin	mitagglutinin	reaction
chemicogenesis	hemolysophilic	munity	sensibilisinogen
		neuorecurrence	seroprognosis

PATHOLOGY, BACTERIOLOGY, PHYSIOLOGY

acidosis index	Döhle's inclusion bodies	hexachromic	neurobion
amicroscopic	exteroceptor	isosmotic	oscillograph
anaplasma	gastrogenic	leukopoiesis	parameningococcus
aprogenous	geneticist	lochiocyte	peripheromitter
bio-assay	goitrogenous	megaloplastocyte	sino-atrial
bionecrosis		mitter	Spiroschaudinna

DISEASES, PATHOLOGIC CONDITIONS, ETC.

adrenalemia	carcinoma	hetero-erotism	neurothecitis
adminosuria	mastitoides	hyperorchidism	oligodyspsia
amylophagia	cleidocranial	hypodynania	orthotyphoid
anaerosis	dysostosis	meso-appendicitis	periejunitis
auricular flutter	dysgenitalism	Mönckeberg's	phrenodynina
bilirubinemia	hemicanities	sclerosis	somopsychosis

SURGERY

aperiosteal	duodenojejunostomy	Lane plate	proctoalvotomy
amputation	epididymotomy	laparogastroscopy	pyeloplasty
autodrainage	ethmoidectomy	Matas' band	pylorodilator
autograft	exothymopexy	Mayo-Robson's point	radiocotomy
Brewer's operati	fascioplasty	myonephropexy	sclerectomy
cardiectomy	isoplastic graft	pluropneumonolysis	ureterostomosis
cecogismoidostomy			venoperitoneostomy

NEW METHODS OF DIAGNOSIS AND TREATMENT

arsenionization	Friedmann's treatment	microkine-	splenodiagnosis
bromatotherapy	immunodiagnosis	matography	stereorönt-
chromoureteroscropy	immunotherapy	salvarsan milk	genograph
endocrinology	irrigoradioscropy	nucleo-analysis	synthescope
esophagogas-	laparogastroscopy	palatography	transendomoscropy
troscopy		pneumatophor	uvulize

Octavo of 1107 pages, with 331 illustrations, 11 in colors. By W. A. NEWMAN DORLAND, M.D., Member Committee on Nomenclature and Classification of Diseases, American Medical Association. Flexible leather, \$4.50 net; thumb indexed, \$5.00.

W. B. SAUNDERS COMPANY

Philadelphia and London

Now Ready--A New Volume

In The International Chemical Series

DR. H. P. TALBOT, Consulting Editor

Quantitative Analysis

By EDWARD G. MAHIN, Ph.D.

Associate Professor of Chemistry in Purdue University

500 pages 5½x8 Illustrated \$2.00 (8/4) net Postpaid

A book that is broader in scope than the usual text.

It aims to produce in the mind of the student a clear comprehension of the scientific development of quantitative methods.

The general discussion is unusually complete, although elaborate or involved theoretical discussions have been, so far as possible, avoided.

The author aims to impress more clearly the principles mentioned in the text, by carefully selected references to original papers.

The mathematical development of quantitative

calculations is unique and a departure in that the "rule of three" has been carefully excluded.

The subjects covered are:

I—General Principles. II—Gravimetric Analysis. III—Experimental Gravimetric Analysis. IV—Electro-Analysis. V—Volumetric Analysis. VI—Color Change of Indicators. VII—Standardization. VIII—Experimental Volumetric Analysis. IX—Oxidation and Reduction. X—Titrations Involving the Formation of Precipitates. XI—Analysis of Industrial Products and Raw Materials.

WHITE—Technical Gas and Fuel Analysis

PUBLISHED SEPT. 1, 1913

By ALFRED H. WHITE, Professor of Chemical Engineering, University of Michigan. 276 pages, 5½x8. 47 illustrations. \$2.00.

A complete and exact modern treatise of service in commercial practice as well as in teaching. It has been adopted already in a number of schools.

LORD & DEMOREST—Metallurgical Analysis

PUBLISHED SEPT. 1, 1913

By the late NATHANIEL W. LORD and DANA J. DEMOREST, Professor of Metallurgy, Ohio State University. Third Edition. Revised, Reset and Enlarged. 330 pages, 5½x8. Illustrated, \$2.50.

Prof. Demorest's revision of the late Professor Lord's "Notes" has been well received. It covers selected methods for the analysis of iron and steel and of the materials used in their manufacture, as well as the analysis of gases, fuels, water for boiler supply, etc.

NORRIS—Organic Chemistry

PUBLISHED NOV., 1912

By JAMES F. NORRIS, Professor of Chemistry, Simmons College, Boston, Mass. 566 pages, 5½x8. Illustrated, \$2.50.

Among its distinctive features are the emphasis on applications, the problems at the end of each chapter, the clear discussion, and the presentation of thoroughly recent conclusions and data. It has had a gratifying reception.

CADY—Inorganic Chemistry

PUBLISHED OCT., 1912

By HAMILTON PERKINS CADY, Professor of Chemistry, University of Kansas. 606 pages, 5½x8. Illustrated, \$2.50.

A distinctive attempt to make an advance in methods of instruction. It is the result of a logical rearrangement of the subject matter which has been tried out by the author for several years in his classroom work.

THE STUDY OF THE STARS¹

THE object of the American Association is the advancement of science. This is a very different matter from the diffusion of human knowledge. The universities and colleges provide liberally for the latter subject, but neglect the former almost entirely. Science is advanced by many individuals who hold offices in the universities, but seldom as a part of their official duties. Few professors are allowed to regard research as a portion of their college work, and still less frequently are appropriations made or funds provided for original investigation. Astronomy is almost the only exception to this rule, and even here in general, the time of the officers is mainly devoted to teaching. Observatories devoted to research like McCormick, Lick and Harvard are supported by funds given specifically for their use, and receive little, or no aid, from the general funds of the universities with which they are associated. It is probable that American universities devote one hundred times as much money to the diffusion of human knowledge, as to its advancement. The great progress made in America in some departments of astronomy is due to the fact that certain wealthy men and women have been willing to give large sums of money for this object. No other country is so fortunate in this respect, although in recent years in Germany large appropriations are being made by the government for similar purposes.

The income of certain funds like the Elizabeth Thompson, Bache and Watson

¹ Address of the President of the American Association for the Advancement of Science, Atlanta, December 29, 1913.

funds is also available, but while these are of the greatest value in aiding particular individuals, the amount is too small to materially advance the entire science. The large funds which might aid individual research are unfortunately employed for other purposes. Scarcely any appropriations have been made to women from these funds. One of the greatest needs of science in America is a fund of moderate size, capable of aiding the men of real genius. The number of such men is not large, and a judicious distribution of a few thousand dollars annually would probably yield greater results than could be obtained in any other way.

A visit to Europe last summer in order to attend the meetings of two national and two international astronomical societies, enabled me to visit several of the larger observatories and to interchange views with the leading astronomers of the world. I have accordingly selected as my subject for this evening "The Study of the Stars," and I shall endeavor to transmit to you the latest views as well as the history of this department of human knowledge. It is my wish to present to my professional friends certain facts of a technical nature, and at the same time to make these clear to those of my hearers who have no previous knowledge of the subject. Astronomy has been called not only the oldest of the sciences but that which has conferred the greatest benefits on man by rendering international commerce possible. While this may be true of the past, the value of the astronomy of the present day lies in its extension of human knowledge and enabling the mind of man to traverse fields which until recently appeared to be hopelessly beyond his ken.

The first catalogue of the stars was made by Hipparchus about B.C. 128, and was inserted by Ptolemy in the "Almagest," for

fourteen centuries the authority in astronomy for the world. This catalogue, which contained more than a thousand stars, gave both their positions and brightness. The earliest copy that is known of the "Almagest" is in the Bibliothèque National in Paris. It is a beautiful manuscript in uncial characters of the ninth century. The other later manuscripts unfortunately differ from it and from each other, so that there is some uncertainty regarding two thirds of the stars, owing to errors of copying. A careful study of these discrepancies has been made by Dr. Peters, of Clinton, and Mr. Knobel, of London. Each spent several years on this work, and all the papers are in the hands of Mr. Knobel. He is now preparing the entire work for publication and it is hoped that it will be in the hands of the printer in a few months.

A manuscript of nearly the same age is in the library of the Vatican, and this year a revised edition of it has been published. If we had a correct copy of the original work, it would have a great value at the present time. Half a century ago it would probably have given the best existing values of the proper motions of the stars which it contained, but recent observations enable us to compute their positions in the time of Hipparchus, more accurately than he could observe them, assuming that the motion was rectilinear. This work might, however, throw light on a possible curvature of the motions. The observations by Hipparchus of the light of the stars have a value that will be considered later.

The first accurate measures of the positions of the stars were made in the middle of the eighteenth century. The catalogue of Bradley in 1755 is even at the present time one of the best means of determining the early positions of the stars. A large number of similar, but later, observations by Hornsby are still unpublished. During

the next hundred years the meridian circle, which is at present the standard instrument for determining the places of the stars, was gradually evolved. In this instrument, a telescope is mounted so that it will point only to stars in the meridian, that is, to stars exactly north or south of the observer. The declinations of stars, corresponding to the latitude of points on the surface of the earth, are then measured by a finely graduated circle. Owing to the motion of the earth all stars cross the meridian twice during every twenty-four hours. The right ascension, corresponding to longitude, will be given by the time of transit. At first, this time was found by the "eye and ear" method in which the observer counted the ticks of an accurate timepiece and compared them mentally with the instant at which the star appeared to cross a wire in the field of view of the telescope. About the middle of the nineteenth century a great advance was made by recording the time electrically on a chronograph. This method was known for many years as the "American" method, owing to its introduction and general adoption in this country. This continued to be the standard method almost to the present time, and an enormous number of observations have been accumulated in this way, the total cost amounting to millions of dollars. Perhaps the most valuable work of this kind is that of the *Astronomische Gesellschaft*, which, by international cooperation, secured accurate observations of the positions of one hundred and sixty-six thousand stars. All stars of the ninth magnitude, and brighter, north of declination -23° are included. Of the twenty zones, seven were observed in Germany, four in the United States, three in Russia, one each in Algeria, Austria, England, Holland, Norway and Sweden. Of the American zones, one was observed at Albany, one at Washington,

and two at Cambridge. Each of the latter occupied the time of an observer and several assistants for twenty years. It was expected that these stars would be re-observed after an interval of about fifty years, to determine the proper motions, or annual changes in position. As the time is approaching when this great work should be undertaken, careful consideration should be given to it. Fortunately, the twentieth century has already developed two new methods which might replace the older plans. The first of these is the transit micrometer, in which a motion is given to the wire in the field of the telescope so that it shall follow closely the motion of the image of a star as it transits through the field. A wide difference of opinion exists among leading astronomers as to the best method of securing this motion. In the earlier instruments constructed by Repsold, the motion was given by a screw turned by the two hands alternately. This method certainly gives excellent results and is still used largely in geodetic work. Any one who has tried it will find that with the rapid motion of an equatorial star under a high power it is difficult to satisfy himself that the wire always bisects the star. If clockwork is used, the rate must vary with the declination and it is strange that this is not done by electrical control, instead of the somewhat crude mechanical devices now employed. The wire records its position automatically on a chronograph at short intervals. The plan of permitting this record only when the observer is satisfied that coincidence takes place, as is done at Heidelberg, seems a good one. Evidently a certain relative motion will give better results than a greater or less motion. It would appear to follow logically that this apparent motion should be given to all stars and the record permitted only for the few seconds of apparent coincidence. We can

expect no better results than those obtained with a filar micrometer. The best plan may therefore prove to be to give a motion to the wire nearly equal to that of the star, whatever the declination of the latter, by a suitable variation of the clockwork. The best rate could readily be determined by observing stars at different distances from the Pole. Successive settings should then be made as with a filar micrometer, closing the circuit on the chronograph only when the bisection was satisfactory. A similar setting should also be made for the declinations. The two coordinates could thus be determined with an accuracy substantially the same as that of a filar micrometer. Experience has shown that one star a minute can be observed in both coordinates with the transit micrometer. There can be little doubt that positions could thus be obtained with much greater accuracy than by the methods now in use. The special advantage would be the elimination of systematic errors.

A second method of determining positions, recently developed at the Allegheny Observatory, is by plates taken with a photographic doublet. Ordinary plates must be replaced by those of plate glass. By taking suitable precautions positions may be determined of even the faintest stars, with an accuracy at least equal to that of a meridian circle. To obtain the best results, the field should be about five degrees square on an 8×10 plate. The focal length of the telescope would accordingly be about two meters. The large field would permit the constants of each plate to be derived from stars as bright as the eighth magnitude. The economy of this method would be very great, as compared with a meridian circle. The usefulness of the latter instrument appears to be confined to observations of the brighter stars. Accordingly, its aperture may be reduced.

The ideal plan would apparently be to divide the sky into regions five degrees square and select in each, five or more stars of about the eighth magnitude and of approximately the same class of spectrum as Class K, so that all should have about the same color. The positions of these should be determined with the greatest possible accuracy with meridian circles, as described above. Some brighter stars should be included to render available the vast number of observations of these objects made in the past. Positions of the stars in the *Gesellschaft Catalogues* and all fainter stars should be determined photographically.

Various attempts are now being made to determine the absolute positions of the stars by means of photography. It appears probable that a pier placed under ground will remain free from irregular motions, and that if this can be accomplished, the absolute positions of the stars near the equator can be found by photography. To determine the equinox, Venus and Mercury should be photographed as well as the sun. By the very satisfactory cooperation of the Princeton, Yale and Harvard observatories the position of the moon is now determined by photography. The results of a preliminary discussion indicate an accuracy at least equal to that of the best meridian determinations, those of the Greenwich Observatory.

Excellent progress is also being made in determining the parallax of the stars by photography. The recent increase in accuracy is at least ten fold, or that of another place of decimals. A hundredth of a second of arc can now be determined with greater accuracy than a tenth of a second, twenty or thirty years ago.

The just criticism has been made of American astronomers that while they have contributed more than their share of

the work in astrophysics the older science of astronomy of position has been greatly neglected. This is partly due to the fact that much of this work has been left to the United States Naval Observatory, which in the past has failed to justify the liberal appropriations made for its support. While Congress has given it for many years a much larger income than that of any other observatory in the world, the law has been such that it is impossible to attain the best results. The superintendent must be a naval officer, instead of an astronomer, and even then must go to sea after a short term. Accordingly, the Naval Observatory during a period of 37 years had 20 superintendents with an average term of less than two years. The Greenwich Observatory during a period of 235 years from 1675 to 1910 has had 8 astronomers royal with an average term of 29 years. The work of the latter institution with but half the income has greatly exceeded that of the Naval Observatory. It should be stated, however, that within the last few weeks, the Naval Observatory has established an admirable wireless time service by which any one can obtain, at trifling expense, accurate time within a tenth of a second. The Navy has no need of a great observatory, from which it derives but little credit. Three successive boards of visitors have pointed out the present unfortunate conditions, but the necessary action has not been taken by Congress. The obvious remedy is to remove the observatory to another department, or place it under the direction of the Smithsonian Institution, and appoint an astronomer at its head. What grander field of work could be undertaken by this observatory than that desired by astronomers and neglected elsewhere. For instance, computers of double star orbits are continually complaining that while a sur-

plus of measures of the easy objects are available, many difficult objects are neglected, although measures of them are greatly needed. The same is true of the asteroids, of variable stars, and in fact in almost every department of astronomy. By making the observations desired by experts, every hour would be saved, and work of the greatest value accumulated.

Astrophysics assumed prominence as a science about forty years ago, although it was foreshadowed by certain far-seeing astronomers like the Herschels, G. P. Bond, Huggins, Draper and others. One department, the study of the light of the stars, was developed much earlier, originating in the *Almagest* and its revision a thousand years later by Sûfi. These catalogues show that the relative brightness of the stars has not changed sensibly during the last two thousand years. Also, that the human eye has the same sensitiveness to different colors, now as then. Stellar brightness was made a precise science by that great astronomer, William Herschel. His six catalogues, two of which remained unknown for eighty years, give precise measures of the light of the three thousand stars contained in them with an accuracy comparable with recent work.

In 1877, stellar photometry was taken up on a large scale at Harvard. Since then, more than two million photometric settings have been made. A station in Arequipa, Peru, permitted the southern stars to be observed on the same system as the northern stars. We have now, accordingly, measures of about eighty thousand stars, including all of the seventh magnitude and brighter, many of the ninth magnitude, and some as faint as the thirteenth magnitude. The excellent work of the Potsdam Observatory gives measures of the light of fourteen thousand stars including all northern stars of the magnitude 7.5, and

brighter. The Potsdam and Harvard systems agree admirably if a correction is applied for the color or spectrum of the stars. They should never be combined, or compared, unless this correction is applied.

Stellar photography, originating in the work of George Bond in 1857, has revolutionized many departments of astronomy. The great work of a chart of the entire sky, undertaken by the Paris Observatory in cooperation with several others, is a sad example of the danger of undertaking a work on too large a scale. Although several observatories have been continually at work upon it for a quarter of a century, it has been predicted that at least fifty years must elapse before it is completed, and no positions of any southern stars have yet been published. In striking contrast to this is the early completion of the Cape Photographic Durchmusterung which gives the positions and magnitudes of nearly half a million stars south of -19° . It illustrates the results of the happy combination of skilful planning with routine organization, conducted on a very large scale. The extension of this work to the North Pole is now being planned, but with the additional condition that the color index as well as the photographic magnitude will be determined. The former will be found by photographing the stars by means of their yellow or red, as well as with their blue, light, the difference in the magnitudes giving the color index. Much might be said of the numerous applications of photography to the determination of stellar magnitude. The sixty-inch reflector of the Mount Wilson Observatory, using exposures of several hours, has succeeded in photographing stars as faint as the twentieth magnitude. An international committee, with members from England, France, Germany, Russia, Holland and

the United States, has adopted a scale of magnitudes based on two investigations made at Harvard. One of these was made with the meridian photometer, and the other is an elaborate investigation by Miss H. S. Leavitt of the photographic magnitude of seventy-six stars near the North Pole. A standard scale is thus provided from the first to the twentieth magnitude. We may say from the minus twenty-sixth to the twentieth magnitudes since accordant results for the light of the sun have been obtained by Professors W. H. Pickering and E. S. King. For many purposes, photography may well replace visual photometric measures, since for stars brighter than the fifteenth magnitude photographs may be taken with yellow light. One of the principal uses of measures of the light of the stars is the study of the variables, or those in which the brightness is not constant. A bibliography of these by Miss Cannon is recorded on about forty thousand cards. The number of known variables is now about forty-five hundred, of which three quarters have been discovered by photography, at the Harvard Observatory. There are several kinds of variable stars. Variables of long period undergo changes which repeat themselves somewhat irregularly in a period of several months, and at maximum are often several thousand times as bright as at minimum. The most useful work that an amateur can do with a small telescope is the observation of these objects. An important work undertaken by the British Astronomical Association has been the observation of variable stars. During the last thirteen years they have accumulated twenty thousand such observations, all reduced to the same scale, which is that of the Harvard Photometry. Similar work in this country has accumulated ten and sixteen thousand observa-

tions in the last two years, respectively. Variables of short period complete their changes in a few days, or hours. Professor Bailey has found five hundred such objects in the globular clusters. In one of these clusters, Messier 3, out of a thousand stars one seventh are variable, all have a period of about half a day, and their periods are known within a fraction of a second. Their light changes so rapidly that in one case it doubles in seven minutes. It is a strange thought that out of a thousand stars, looking exactly alike, there should be a hundred little chronometers keeping perfect time, and whose rate is known with such accuracy. About a hundred and fifty variables belong to the Algol class, in which the light is uniform for a large part of the time, undergoing a sudden diminution at regular intervals. This is due to the eclipse of two bodies, one darker than the other, revolving around their common center of gravity. An elaborate theoretical study of this problem has been made at the Princeton Observatory and, largely from the photometric and photographic magnitudes made at Harvard and elsewhere, the dimensions of a large number of these systems have been determined.

Photography still can scarcely compete with other methods where the greatest accuracy is desired, as for instance, the measures with the polarizing photometer by the late Oliver C. Wendell. The masterly use of the selenium photometer by Professor Stebbins gives results for bright stars of still greater accuracy, while the experiments in Germany with the photo-electric cell by Rosenberg and Guthnick give results which promise to revolutionize our present methods. The principal source of error appears to be the varying transparency of the air. The trial of the instru-

ment in a location where the air is exceedingly clear and steady for long periods is greatly to be desired.

During the last twenty-five years photographs have been obtained by the Harvard Observatory in order to furnish a history of the stellar universe. Two similar 8-inch photographic doublets have been used, one mounted at Cambridge for the northern, and the other at Arequipa for the southern stars. With each of these instruments about forty thousand photographs have been taken. The total weight of these plates is about forty tons. As each plate covers a region ten degrees square, every part of the sky has been photographed, on the average, a hundred times. This work is now supplemented by two small Cooke anastigmat lenses, each having a field thirty degrees square. The number of plates taken with these two instruments are nine thousand and fourteen thousand, respectively. The exposures with the larger instruments are, in general, ten minutes, showing stars of the thirteenth magnitude. The exposures with the smaller instruments are one hour, showing stars of the eleventh magnitude. A continuous history of the sky is thus furnished from which the magnitude and position of any stellar object of sufficient brightness can be determined for a large number of nights during the last quarter of a century. A striking illustration of the value of this collection occurred when the planet Eros was discovered in 1898. It appeared that this object was nearer the earth in 1894 than would occur again for thirty-five years. An examination of the photographs showed its presence on 23 plates, and from their positions the parallax of the sun and mass of the earth were determined with an accuracy equal to that of any of the methods previously used, and on which an

enormous amount of time and money had been spent.

For many years the Kiel and Harvard observatories have served as distributing centers of astronomical discoveries and observations in Europe and America, respectively. The last new star which is known to have appeared, Nova Geminorum, No. 2, was discovered by Enebo at Dombass, Norway, on Tuesday, March 13, 1912. The cable message was received at Cambridge Wednesday morning, and the star was observed at several American observatories the next evening, or the night following its discovery. An examination of the Harvard photographs showed that two plates had been taken on the preceding Sunday, March 11, on which no trace of the Nova was visible, and two on Monday, March 12, showing it of nearly its full brightness. Photographs taken Wednesday compared with those obtained a few days later showed the wonderful change in its spectrum, from the solar type with dark lines, to the typical spectrum of a Nova with bright lines.

There is no department of astronomy which is now receiving greater attention than the study of the spectra of the stars. Dr. Henry Draper was the first to photograph the lines in a stellar spectrum, although Sir Williams Huggins had already obtained a mark from the spectrum of Sirius, and later was the first to publish his results in successfully photographing stellar spectra. The untimely death of Dr. Draper, in the midst of his work, led to the establishment at Harvard of the Henry Draper Memorial. For nearly thirty years Mrs. Draper has maintained an active interest in this work. By placing a large prism over the objective of a telescope, the light of all the brighter stars in the field are spread out into spectra, so that instead of photographing the spectrum of

one star at a time, as with a slit spectro-scope, as many as a thousand have sometimes been taken on a single plate. Such photographs, covering the entire sky, have been taken with the two 8-inch doublets already mentioned. A study of the spectra thus obtained enabled Mrs. Fleming to discover many hundred objects whose spectra are peculiar. Among them may be mentioned 10 of the 19 new stars known to have appeared during the years in which she was engaged in this work, while five of the others were also found at Harvard by other observers. She discovered more than two hundred variable stars, 91 out of the 108 stars of the very peculiar fifth type, and showed that these objects occurred only very near the central line of the Milky Way. During the last two or three years a great demand has arisen for the class of spectrum of large numbers of stars. The Harvard photographs show the class of spectrum of nearly two hundred thousand stars. Miss Cannon has, accordingly, undertaken to prepare a catalogue of these objects, with the result that she has already classified about one hundred and fifteen thousand spectra, covering more than one half of the sky. The work is progressing at the rate of five thousand stars monthly, and the results will fill seven of the large quarto *Annals* of the Harvard Observatory. The organization of this work has required the most careful application of the principles of "scientific management."

One of the most important results derived from the Harvard photographs was the discovery that in certain spectra the lines were alternately double and single. This, and the discovery by Vogel at Potsdam that the lines of the variable star Algol continually changed their position revealed the existence of spectroscopic binaries. No department of astronomy is

receiving more attention, at the present time, than these objects, and in general the motion of the stars in the line of sight. The Lick, Yerkes, Greenwich, Potsdam, Bonn and Ottawa observatories are only a portion of those directing a large part of their energy to this subject.

One of the most important generalizations of recent times is the discovery by Professor Campbell that the velocity of a star depends upon its class of spectrum. The proper motion of a star was similarly found by the late Lewis Boss to be dependent on the same quantity.

In conclusion, the United States has attained an enviable position in the newer departments of astronomy. Can this be maintained? In Europe, especially in Germany, observatories and instruments of the highest grade are now being constructed, the government furnishing appliances with the most liberal hand. Perhaps the most promising sign for the future is the friendly cooperation of American astronomers, which has never been more marked than at the present time.

The possibilities of work are now greater than ever before. A small fraction of the effort expended in teaching science if devoted to its extension and progress would fulfil the objects of the American Association for the Advancement of Science.

EDWARD C. PICKERING

PROGRESS OF THE CHEMISTRY OF AGRICULTURE¹

It is the object of this address to present briefly the important recent advances made in agricultural chemistry. In so doing, it is not my intention to go back one hundred years or fifty years or even to the period included in the memory of

the veterans of this association; but only to consider such a period as is within the memory and the experience of a youngster like myself.

Agricultural chemistry is so closely interwoven with the other sciences which have been applied to agriculture, that it is practically impossible to disentangle them. Hence, to a certain extent, the progress of the chemistry of agriculture is closely related to the progress of other agricultural sciences, and to agricultural science, in general. The contributions of the chemist to agricultural science have been so many, so varied and so important, that for a long time the sciences applied to agriculture have been termed agricultural chemistry. This period is passing, and the term agricultural chemistry is being more restricted in its significance, but the field is still broad, and the harvest bountiful to the worker who seeks to garner the grain of knowledge.

There has been a tendency in some colleges to discontinue the teaching of agricultural chemistry, and to divide the subject-matter between the agronomist and the animal husbandman. It is a serious question whether such tendency is in accord with the known laws of specialization in science. There is no doubt but that, as time goes on, the agricultural chemist must specialize more and more in one of these fields of work, but there is a difference between the specialization of the scientist in his own field, and the attempt of other branches of agricultural science to take over the work of the chemist, or the chemist to take over other branches of agricultural science. As I see it, both the agronomist and the animal husbandman have their special problems. They must have their special training in their own fields, and while this training must include some chemistry, it is not sufficient in quantity to

¹ Presidential address before the Association of Official Agricultural Chemists of North America (November 18, 1913).

make them into chemists in addition. On the other hand, the chemist must be, first of all, a chemist. The agricultural chemist must have knowledge of soils and animal nutrition, but he should have predominant chemical training and chemical methods of thought. The agronomist and the animal husbandman undoubtedly need the aid of the chemist in the solution of their problems; but they should not seek, at one and the same time, to be both agronomist and chemist. The result of such an effort is either an agronomical chemist or a chemical agronomist. It often results in the chemist becoming also the agronomist. What agricultural science needs is the highly-trained agronomist, working, where needs be, in cooperation with a highly-trained chemist who has perhaps specialized in soils and fertilizer chemistry, each assisting and aiding the other. The same is true of the animal husbandman. We need the animal husbandman, highly trained in his field and with a full knowledge of its peculiar problems, working in cooperation with the agricultural chemist, highly specialized in the chemistry of animal nutrition. In this way, we shall avoid those errors which we so often see when a man enters into a field outside of his special training—errors which the specialist immediately recognizes. The truth of the matter is, that the chemist has made such great contributions to the field of agricultural science, that the agronomist and the animal husbandman have, in many cases, not been able to see their own peculiar problems, but have emphasized the chemical side of the subject. They have not wholly found themselves. In some institutions, agricultural chemistry is no longer taught. This, we believe, is a mistake. The student needs a thorough grounding in the entire field, such as is given by the agricultural chemist, and he needs to look

at agriculture, for a time, from the point of view of the chemist. Specialization should come later.

These matters will adjust themselves in time. We need not fear that the science of agriculture will ever be without the need of the agricultural chemist. Our ranks have not thinned, but each step of progress has rather added to our numbers. The Adams Act, for example, which is one of the most important events in the recent history of agricultural science, has increased the number of agricultural chemists, as well as the number of other agricultural investigators.

The Adams Act, of March 16, 1906, is important, not only from the fact that it increased the number of scientific agricultural workers in the experiment stations, and their facilities for investigation, but because it affords to the experiment stations opportunity for fundamental research work. The passage of the Adams Act indeed marked an epoch in the history of agricultural science. The experiment stations had previously done much valuable work, and accumulated much data, a fact which the passage of the Adams Act itself recognizes. But the experiment stations had such large demands upon them for immediate and practical information, that they had little time for the investigation of fundamental things, no less practical in their final application, but requiring more time, more patience and less obvious in their practical applications. But under the Adams Act, the experiment stations not only may, but must, conduct research. Fundamental and continuous work may be done upon projects which have no present popular appeal, though no one can predict the ultimate effect of such work. The result of the Adams Act has been an increase in personnel and in facilities for the experiment stations, and it has aided in

creating a demand for more highly trained research assistants. It has also tended to raise the standard of scientific publications of the stations. Thus, as I said, with the passage of the Adams Act, the experiment stations entered upon a new period of their existence, one in which fundamental research becomes a much greater portion of their functions than has been the case in the past. It is true that some directors of stations, and some governing boards, do not yet understand the true significance of research, or the qualifications necessary to pursue it. It is true that some station men do not, in their publications, give proper references to previous work, which may have anticipated their own. It is true that in bulletins and in reports of directors, we sometimes find claims of credit for work which are exaggerated, or perhaps the credit belongs elsewhere; claims which are hardly pardonable, even after making all possible allowance for natural exaggerated opinions of one's own work. Such things will pass away. We need more criticism of our agricultural publications—not destructive criticism, but friendly criticism, and friendly controversies over disputed points. Criticism of the proper kind is a stimulant to good work, and aids in pruning away excrecences such as those mentioned above.

The Adams Act created a demand for men capable of research in agricultural chemistry, and other lines of agricultural science. Research is not an ordinary qualification, even in young men just graduated from college. The ability to do research work must be founded upon a natural ability and inclination towards such work, developed by broad general training, and wide knowledge of some particular science, and by an apprenticeship under one who is himself a master of research. This apprenticeship may be during a course of

work and study for the degree of Doctor of Philosophy; but it may also be in the process of regular station work under some eminent station investigator. We must recognize the fact that all men capable of research have not been able to secure the Doctor's degree, even though they have done equivalent work. The ability to do research work may be developed by study and training, but it can not be created.

The Adams Act thus marks an important step in the progress of agricultural chemistry, other agricultural sciences and agriculture, as a whole. Perhaps equally as significant was the passage of the National Food and Drugs Act, approved June 30, 1906. Taken in a broad way, the passage of this act was one of a series of events in the reaction of the people against dishonest commercial practises. It has become evident that the people will no longer tolerate practises which have crept into use, which are morally wrong, but were formerly considered as all right because they were business; practises which deceive the buyer or give unfair advantages in business competition. Business has been a species of warfare, but just as it is now contrary to the laws of civilized warfare to kill women and children and burn private dwellings, so it is becoming contrary to the laws of business warfare to cheat women and children and to deceive the purchaser as far as possible. How much the agitation for the pure food and drug law had to do with this moral awakening, no one can say, but no doubt this crusade of twenty-two years had much to do with it—a crusade by an agricultural chemist, Dr. Harvey W. Wiley, for many years chief of the Bureau of Chemistry; secretary of the Association of Official Chemists from its organization until only a little more than a year ago, now our hon-

orary president—for whom all of us have a warm place in our hearts.

The Food and Drugs Act has resulted in a material clearing of the atmosphere, with respect to the naming, labeling and adulteration of foods, drugs and feeds. We now have very clearly defined the objects of such a law. These are, first, to prevent the sale of any unwholesome or deleterious substance, and second, to ensure that the goods delivered to the purchaser shall be exactly as represented. These principles have been made clear, not only with respect to foods and drugs, but also with respect to feeds, and feed manufacturers are beginning to realize that a mixture of bran and screenings may no longer be sold as bran, or a mixture of corn bran and corn chops, sold as corn chops. There are some feed manufacturers who have not yet read aright the signs of the times, as, for example, some of the manufacturers of cottonseed meal, who contend for the authority to sell a mixture of meal and hulls under the name of cottonseed meal, but undoubtedly the time will come when this matter will be made clear.

This association has played an important part with respect to food adulteration. Before 1900, there was one referee and one associate on this subject. At the 1900 meeting, provision was made for 14 associate referees, and there are now 21 associate referees. In addition, we have our committee on food standards, which has done valuable work.

In the matter of cattle feeds, their analysis and adulteration, it appears this association has done little in recent years. The analysis and control of these feeds are yearly assuming a greater importance. There should be a referee and an associate referee on the adulteration of feeds and methods for their detection. We have no official methods on this phase of the

subject, beyond the ordinary analysis. The method for crude fiber should be thoroughly studied, and perhaps modified. The clause which permits filtration through cloth should be eliminated. The estimation of crude fiber is becoming more and more important, for by its use we can detect more easily the addition of materials rich in crude fiber, to concentrated feeds. The estimation of crude fiber, for example, shows much more clearly the probable quantity of cottonseed hulls in cottonseed meal, or rice hulls in rice bran, than does any estimation of protein and fat.

Striking progress has been made in recent years in the study of soils. This applies especially to the survey and mapping of soils. In this work, the Bureau of Soils is easily the leader. There is a tendency in some quarters to regard the survey, mapping and analysis of soils as an end in itself. It is true that such work is highly important, but it should also be regarded as a basis on which to make further soil investigations so that we may become fully familiar with the properties and characteristics of each type. In a sense, the soil survey should be regarded as the beginning of soil studies.

In other respects our knowledge of soils has been increased by recent investigations. We now know more concerning the nature and constituents of the organic matter of the soil, and something more concerning its biological properties. We also know that, on an average, the needs of the soil for fertilizer nitrogen in pot experiments is related to the total nitrogen of the soil. We know that the active potash of the soil is related to the average needs of the soil for potash in pot experiments, and that plants have the power to exhaust the active potash and to take up more potash than they need. We know that, on an average, the active phosphoric acid of the soil is re-

lated to the needs of the soil for phosphoric acid in pot experiments. The relation of the pot experiments, and the analysis, to field needs, must be worked out. Soils also deviate from the average, as regards their plant food content and behavior to pot experiments; such deviations must be studied and their causes ascertained. There is much to be done, but progress is being made.

In the field of animal chemistry, decided progress has been made in recent years. We must now recognize the possibility, that, in digestion, proteids of different kinds may be split into different products, some of which may be unfit for use as structural material in building up animal proteids, and so must be discarded. We know that this is possible, but we have not yet secured positive evidence that such occurs with any of the various proteids fed domestic animals. Such studies may be expected in the future.

It has been shown, without doubt, that the digested materials of different feeds have different values to the animals. One pound of digestible nitrogen-free extract in corn has a much greater value than one pound of digestible nitrogen-free extract in straw. The fact that there is a difference in the values of digested nutrients of the same class but from different feeds has been clearly shown by the work of Kellner and of Armsby. There is no doubt about it. It is a step forward to recognize the differences in the values of the digested nutrients and to adjust our tables, our rations and our calculations accordingly. There is abundant room for work along this line, but enough work has already been done to justify this advance. Nearly every American book which deals with the feeding of animals still assumes that the digestible nutrients of one feed are equal in nutritive value, pound for pound, to

the digestible nutrients of the same class in any other feed. These books must be re-written and adjusted to our latest advances in knowledge. This advance will, to a certain extent, reconcile the differences between the effects of feeds or of rations in feeding experiments which, under the old standards, should have apparently the same nutritive values.

We are now able to state the nutritive value of a feed in terms of three factors: its bulk, which satisfies the hunger of the animal; its proteids, which repair flesh or tissue, or which, in excess, may be used for fat or energy; its fat-producing value, which is its ability to furnish the animal with heat or energy or to form fat. The fat-producing value of a feed or nutrient is determined experimentally. First, the fattening animal is fed a ration which produces a slight gain of fat, and the gain of fat is measured by determining the income and outgo of carbon and nitrogen. Next, the nutrient or feed is added to this ration, and the gain in fat again determined. The difference in the quantity of fat produced is due to the added feed or nutrient.

The results of such work can be readily compared with calculations based on the assumed equality of the same group of nutrients in different feeds. While the calculated value of peanut meal or linseed meal is practically equal to that found, the value for a wheat straw is only 20 per cent. of that calculated, of meadow hay 54 per cent., of rye bran 79 per cent. of that calculated.

It should be clear that the recent advances in the chemistry of animal nutrition compel us to modify materially tables of feeding values, rations, and methods of calculation. There is opportunity for useful and valuable work along the lines of determining exactly the productive values

of feeds and nutrients, and such work may be expected in the future.

In the thirteen years of the twentieth century the progress of agricultural chemistry has been such as to satisfy even the pessimist that we are moving forward. Our facilities for scientific investigation have been increased by the Adams Act. Our supervision over foods, drugs and feeds has been enlarged and rendered more effective through the Federal Food and Drugs Act. We have made great progress in the survey and mapping of soils and in our knowledge of their properties and chemical composition. The science of animal nutrition has made such advances as to render it necessary to revise almost all books dealing with the subject, and to modify our methods of stating the nutritive values of feeds, and our methods of calculating rations for feeding animals. These have been the four chief lines of advance of agricultural chemistry in recent years. The members of the Association of Official Agricultural Chemists may well take pride in the part they have taken in the progress that has been made.

G. S. FRAPS

THE NEW YORK STATE VETERINARY COLLEGE AT CORNELL UNIVERSITY

THIS occasion¹ is to commemorate the opening of a suitable hospital for large and small animals and halls for the teaching of veterinary medicine. It has greater significance than the mere addition of new buildings to our working equipment, for it introduces into the teaching of clinical medicine methods of precision which heretofore could not be employed. We believe it is desirable that the public should know what the university and the state are doing

to increase the efficiency of the veterinary profession.

In the development of veterinary medicine in America, Cornell University holds a conspicuous place. It was the first institution of higher learning to place veterinary medicine on par with other sciences. When its doors opened in 1868, there was among its professors a veterinarian. A department of veterinary medicine was established and it continued as such until 1896. During those twenty-eight years, the head of that department, our distinguished and beloved Dr. Law, was not only an adviser in university affairs, but also a leader in the important work of the nation in eradicating those diseases of cattle that cost Great Britain and her colonies hundreds of millions of dollars. Had it not been for the broad views of Ezra Cornell and President White relative to the teaching of applied sciences in Cornell University, where Daniel E. Salmon, Theobald Smith and Leonard Pearson were trained, the losses on British soil from contagious pleuropneumonia, piroplasmoses and foot and mouth disease might easily have been duplicated in this country.

At the time the department of veterinary science was organized in the university, it was not thought in this country to be necessary to expend large sums of money for veterinary education. The American people experienced with the resignation of the fatalist a steadily increasing loss from diseases of animals. Because of the enormous live stock industry and export trade in cattle and animal products, this loss was not generally felt. The time was approaching, however, when our meat and dairy products would be required to feed our own people and when the losses sustained from disease would be added to the cost of living. This condition was inevitable here as it had been in Great Brit-

¹ Opening of hospital and clinic buildings, New York State Veterinary College at Cornell University, November 15, 1913.

ain and Germany. It was with prophetic insight that the founders of this institution planned to meet the needs of the approaching situation. It was clear to them that when the law of supply and demand raised the price of meat to a certain height it would be necessary to save the thousands of animals that were annually falling victims of preventable disease. In recognition of this, veterinary teaching at the university began in a small way, but from the beginning its growth was assured.

A second advance was made when the university and the state formed a partnership in which the university was to give toward a veterinary curriculum such instruction as it possessed and the state was to furnish the other necessary teachers, buildings and equipment to complete a veterinary college. By this act, the veterinary department was transformed into a college and a greater work was undertaken. The statute establishing the New York State Veterinary College at Cornell University states that its function shall be the pursuit of such researches and the preparation of such diagnostic and prophylactic agents as may be necessary to protect our domesticated animals against disease and to give instruction in veterinary medicine and surgery. The framers of that law saw with great clearness that the live stock interests of the state required for the control of disease men with a thorough training in the sciences upon which the art of medicine rests. They recognized that the high purpose of the veterinary profession was to prevent quite as much as to treat diseases of animals. This required that students of veterinary medicine should have a preliminary education sufficient to intelligently study those sciences which have revealed the nature of disease. To provide for this, the law requires that in order to enter a veterinary college in this state, the

student shall have satisfactorily completed a four-year high school course or its equivalent. This was a long step in advance educationally, although many considered such a preparation unnecessary. There seemed to be a feeling that the successful practise of veterinary medicine in this country did not require the knowledge or discipline that experience had demonstrated as necessary for its success in Europe. However, the great champion of higher veterinary education in this country firmly insisted on the higher entrance requirements. For his perseverance in this cause alone, future generations will look upon Dr. Law as the foremost veterinary educator in America.

This college opened in 1896 with the main building, one story of the north wing and a small clinic building and hospital. These cost the state \$150,000. For reasons mentioned, the number of students was small, a total of eleven, and the faculty consisted of eight teachers. For several years, there were no additional buildings and the students increased in number very slowly. The principle of higher veterinary education was on trial. Finally growth was in evidence. The Flower library was endowed with \$10,000. An operating room was built on the surgical hospital and the second story of the north wing was added. These cost \$27,050. In 1908, the trustees of the university set aside for the veterinary college a farm of one hundred acres for use in the study of animal diseases. And finally, there has just been completed, but not equipped, the hospital for large and small animals and clinic halls for teaching veterinary medicine. These have cost \$140,000. The state has a total of \$317,050 invested in buildings and \$54,000 in equipment. The college, however, is not yet completed. There remain to be added the south wing to the main building and a

diagnosis and pathological laboratory. It is estimated that they will cost \$200,000. While these appropriations may seem large, it is well to know that the little country of Norway, with far less live stock than the Empire State, has recently built a national veterinary college at a cost of 2,300,000 krona (\$644,000) or a hundred thousand dollars more than the plans of this college call for.

The completion of suitable hospitals for large and small animals, clinic halls and diagnostic laboratories adapted to the teaching of clinical medicine justifies our calling this the beginning of the third era in the development of veterinary medicine at Cornell University. The opening of these splendid wards is significant not only from the pedagogic point of view but also from the standpoint of better veterinary service in the state. The thought of the leading educators in human medicine has been that the teachers of medicine should have adequate hospital facilities to study disease in all of its phases and that they should not be distracted by private practise. This ideal toward which our best medical colleges have been striving has been attained in but few institutions. In this particular, we are fortunate. With ample hospital and clinical facilities and men eminently fitted for teaching veterinary medicine, it is confidently expected that greater efficiency will not only characterize the teaching of students but also increase the application of better methods for the treatment, prevention and control of animal diseases in the state. In rejoicing that such opportunities have been provided, we must not be boastful, for in the acquisition of such facilities, the states of Iowa, Ohio and Pennsylvania have led the Empire State. We do rejoice, however, that America is beginning to realize that if the fearful losses from animal diseases are to

be checked here as they are in Europe, veterinary medicine must be taught and practised along equally scientific lines.

The work of the veterinarian is not generally understood or appreciated. It is not the only purpose of a veterinary college to teach men how to treat the accidental ills of animals. In addition to this, the veterinarian has to advise the owners how to protect their flocks and herds from the diseases which are liable to attack them. In New York state there are \$290,000,000 invested in animals. The annual revenue from this investment is \$140,000,000 or nearly two fifths of the total agricultural product of the state. It has been conservatively estimated that the loss from disease is ten per cent. One of the problems for the veterinarian is to save to the live stock industry all that is preventable of the \$29,000,000 loss on investment and to restore as much as possible of the loss in production due to disease. The control of the diseases of animals communicable to man is not a task of small proportions. The inspection of dairy cattle to detect and eliminate those whose milk is dangerous, to inspect the meat from diseased animals that are killed for food, and the many other services of a sanitary, humane or economic significance require a large fund of technical knowledge. It is not my desire to dwell upon the multitude of needed services the trained veterinarian can render but rather to call attention to the efforts that are being made to qualify men for such work.

I have already mentioned the purpose of the founders of this college and the somewhat discouraging outlook at its opening. Starting with an initial enrollment of eleven students in all classes and a faculty of eight, we have now a registration of one hundred and twenty-three undergraduate students and five graduates and a faculty of nine-

teen men who devote their entire time to teaching and research. Knowing that the state would not require a large number of veterinary graduates in any one year, the college was planned, as you can see from your inspection, to teach from fifty to seventy-five students in each class. This is all the veterinarians that the live stock interests of the state will require for many years.

The general tendency toward increased efficiency has been exemplified in this college by the adoption of certain procedures to extend its usefulness. An optional four-year course has been offered and several students are taking it. This was done to make it possible for those who desire to devote more time to their preparation for professional work. We hope in the near future to make the four-year course compulsory. There is a difference of opinion on this point. It is thought by some that it would be better to have one year of university work required for entrance than to have a four-year professional course with the present lower entrance requirements.

A combined course with the college of agriculture has been arranged so that students may receive both degrees in six years. A few students are already taking this course.

The ambulatory clinic was established to enable senior students to visit with an instructor sick animals in the near vicinity of the college. This gives a touch of actual practise in connection with class-room and laboratory work.

In 1908 there was established an annual conference for veterinarians. The faculty appreciated its opportunity to assist the practitioners of the state by introducing a short course of instruction on the most important veterinary subjects of the day. Every licensed veterinarian of the state is invited. Last year fully 15 per cent. of

the active practitioners of the state attended this conference.

In June of this year a course in practical horseshoeing for the horseshoers of the state was authorized. This is under the immediate supervision of an experienced horse-shoer who was trained in the leading schools of Europe.

The research work that is being done at the veterinary experiment station as well as in the laboratories is not only of great value to the live stock owners of the state and of much teaching significance, but it also brings the students in contact with the actual problems with which the practitioner has to deal in the active warfare against disease. It is by these and other methods that the New York State Veterinary College at Cornell University is striving to be a positive factor in alleviating the suffering among domesticated animals and in saving to the owners the losses from disease.

VERANUS A. MOORE

STEREOSCOPIC EFFECTS IN PHOTOGRAPHY

THE exhibition of scientific photography which was recently held at Vienna in connection with the Austro-German Medical Congress contains, according to an article in the *London Times*, an exhibit which marks a great advance in the progress of photography. This is a series of photographs in which true plastic effect is obtained without the employment of a stereoscope or any other optical instrument. For the various objects depicted to stand out in their true relations to one another all that is required is that the picture should be looked at directly and not from one side or the other.

The method by which this result is obtained is, briefly, as follows: A double negative is made in the ordinary way by the use of a stereoscopic camera with twin lenses. Instead of the reconstruction by means of the stereoscope of the plastic image from the

pictures thus obtained the inventors, Herr Friedmann and Herr Reiffenstein, have devised another means of making each eye see only one, and that one its own particular image. This consists of the application of the fact that when placed against a white background the image on a positive transparency is visible and that when seen against a black background it becomes invisible, while should the image be bleached the contrary is the case. From the negatives which have been obtained in the ordinary way with the stereoscopic camera are made, therefore, from one, an ordinary transparent positive, and, from the other, a negative which is afterwards bleached. Let it be assumed that from the negative corresponding to the image seen with the right eye the ordinary positive is made and that the left eye's picture becomes the bleached negative. If these two transparencies were super-imposed one upon the other and laid upon a white background only the right-eye picture would be visible. On the other hand, if placed upon a black background only the left-eye picture would be seen. It is, however, necessary that both eyes should see their respective pictures simultaneously. For this a background is required which to the right eye appears white and to the left eye black. This is provided by a sheet of glass, the back surface of which is prepared in a special manner, while the front surface is ribbed convexly, whereby the rays of light falling upon this surface are broken in such a way as to make it appear black or white according as looked at from one side or the other. The problem is, therefore, solved. The two transparencies are placed one upon the other, and then both upon this background. The right eye sees only its proper image and the left eye likewise. These combine automatically, as is the case when a stereoscope is used, and the result is a true plastic picture.

The inventors exhibit five or six specimens of such photographs to which they have given the name of "stereographs." Three of these appeared to the writer of this article to be almost faultless. One of them represented a

lump of quartz in which even the shimmer on the surface was reproduced; another, a spray of orchids in a vase, and the third, the skeleton of a gorilla. In the other specimens the two images did not seem to combine easily. The inventors are making arrangements for the manufacture in cheap and handy form of "backgrounds" which they hope before long to have brought to such a state of perfection that the process will be generally employed. With such "backgrounds" the inventors state that pictures can be looked at like any other photograph. In the case of the stereographs now being exhibited the effect of the black-and-white background is, however, obtained by a different method, which necessitates their being viewed by transmitted light.

SCIENTIFIC NOTES AND NEWS

THE sixty-fifth meeting of the American Association for the Advancement of Science opened at Atlanta on Monday, Dr. Edmund B. Wilson, of Columbia University, being introduced as president, and Professor Edward C. Pickering, of Harvard University, giving the address of the retiring president on "The Study of the Stars," printed in this issue of SCIENCE. Subsequent issues will contain other addresses and reports of the meetings at Atlanta and of the meetings held simultaneously at Philadelphia, Princeton, New York and New Haven.

M. JEAN PERRIN, professor of physical chemistry of the University of Paris, has been given the degree of doctor of science by Columbia University, to which he is this year visiting professor.

SIR PHILIP WATTS, K.C.B., F.R.S., has received the Order of the Rising Sun (second class) from the Emperor of Japan.

DR. CHARLES DEGARMO, since 1898 professor of the science and art of education at Cornell University, will retire at the close of the next summer session.

THE Senate of the University of St. Andrews has invited Professor J. Arthur Thom-

son, since 1899 regius professor of natural history at Aberdeen, to be the Gifford lecturer for the years 1914 to 1916.

MRS. ELLA FLAGG YOUNG has been reinstated as superintendent of schools by the Chicago Board of Education by a vote of thirteen to seven, the minority of seven declining to cast a ballot.

DR. KEVIN BURNS, of the Lick Observatory, has been appointed to a post in the Bureau of Standards, Washington.

THE Royal Society's studentship on the foundation of the late Professor Tyndall for scientific research on subjects tending to improve the conditions to which miners are subject has been awarded for the ensuing year to Mr. J. I. Graham, of Bentley Colliery, Doncaster, for an investigation into the cause of spontaneous combustion of coal.

DR. LYMAN C. NEWELL, professor of Chemistry, Boston University, has been elected president of the University Club of Malden, Mass.

At the educational conference, held at the University of London, beginning on December 26, twenty-one institutions were represented. Mr. James Bryce delivered the inaugural address, entitled "Salient Educational Issues."

"SCENIC Features of North America from the Geological Point of View" is the general subject of a series of illustrated lectures to be given by Professor Wallace W. Atwood, of the department of geology of the University of Chicago, at the West Side center of the University Lecture Association in Chicago. The series begins on January 3 and ends January 31, one lecture being given each week.

THE following public lectures are announced by the Cornell Chapter of the Sigma Xi: "Recent Investigations in Organic Chemistry," by Professor A. W. Browne, January 19; "Electric Operation of Panama Canal Locks," by John W. Upp, M.E., '89, of the General Electric Company, February 3; "Some General Bearings of Embryology," by Professor B. F. Kingsbury, February 23;

"Electric Waves and Wireless Telegraphy," by Professor Ernest Merritt, March 30; "The Experimental Development of the Art of Sewage Disposal," by Professor H. N. Ogden, April 30; "Some Recent Problems in Geometry," by Professor Virgil Snyder, May 25.

ON November 20, Professor M. A. Rosanoff, of Clark University, gave a talk before the Sigma Xi Society at the Worcester Polytechnic Institute on his scientific experiences at the *Versammlung deutscher Naturforscher* in Vienna last September.

MR. EMERY C. KOLB, of Grand Canyon, Arizona, gave a lecture, illustrated with colored slides and motion pictures, before the Geographic Society of Chicago on December 19, the title being "Photographic Exploration of the Canyons of the Colorado River."

DR. STUART PATON will give a series of public lectures at Princeton University on Thursday afternoons at five o'clock on The Study of Human Activities in Relation to Social, Educational and Ethical Problems. The dates and subjects are as follows: February 12, "The Individual. Life as a Process of Adjustment"; February 19, "Adjustments in the Reflex, Automatic and Conscious Levels of Activity"; February 26, "Synthetic and Inhibitory Mechanisms"; March 12, "The Personality"; March 19, "The Problem of Degeneracy. The Feeble-minded, the Delinquent, the Criminal"; March 26, "The Intelligent Direction of Human Activities. Education"; April 2, "Science and Culture."

At the annual public meeting of the Paris Academy of Sciences, held on December 15, M. Gaston Darboux, the permanent secretary, pronounced a eulogy on Henri Poincaré, the famous mathematician, who died in July last year. The speech included an account of Henri Poincaré's early life.

It is proposed to establish a permanent memorial to the late Sir William White, K.C.B., F.R.S. The Institution of Civil Engineers, the Institution of Mechanical Engineers, and the Institute of Marine Engineers, and other bodies are supporting the plan, and

have invited their members to contribute. A general committee under the chairmanship of Lord Brassey has been formed. The form which the memorial is to take will depend upon the support which is given, about \$7,500 having already been received.

DR. CHARLES BUDD ROBINSON, economic botanist of the Bureau of Science of the Philippine Islands has been killed by natives in the Amboyna Islands in the Malay Archipelago. Dr. Robinson was born in Pictou, N. S., in 1871; he received his bachelor's degree from Dalhousie University in 1891 and his doctor's degree from Columbia University in 1906. He was the author of researches on the economic and systematic botany of the Philippines.

THE death is announced in London on December 15, of Dr. Penry Vaughan Bevan, professor of physical science at the Royal Holloway College.

THE U. S. Civil Service Commission announces an examination for technical assistant in pharmacology, for men only, to fill vacancies in this position in the Division of Pharmacology, Hygienic Laboratory, Public Health Service, at salaries ranging from \$1,800 to \$2,000 a year.

THE next grants from the Elizabeth Thompson Science Fund will be made in February, 1914. Applications should be sent in to the secretary, Dr. Charles S. Minot, Harvard Medical School, Boston, Mass., before February 1, 1914.

THE Edward N. Gibbs Memorial Prize Fund, the income of which amounts to about five hundred dollars, was established by the wife and daughter of the late Edward N. Gibbs, and is used in aiding investigators into the cause and treatment of diseases of the kidney. The recipient of the fund is chosen annually. The committee will select the worker for 1914 about the first of February, and request all persons who desire to work under this fund, to send to the committee of the Edward N. Gibbs Memorial Prize Fund, 17 West 43d Street, N. Y. City, their applica-

tion together with a statement of their fitness to prosecute such investigations, giving the laboratory in which they have studied, and any researches conducted by them, in order that the committee may be guided in the selection of the recipient of the fund for 1914.

THE Colony of the Straits Settlements has voted a sum of £350 to Mr. Chamberlain's fund for the extension of the London School of Tropical Medicine.

News has been received from the Stefansson expedition that the scientific men and members of the crews of the *Alaska* and *Mary Sachs* were safe and well in winter quarters at Collinson Point, fifty miles from Flaxman Island, on the Arctic Circle.

THE Puget Sound Marine Station located at Friday Harbor, Washington, will be open next summer under the directorship of Professor Theodore C. Frye, the head of the department of botany at the University of Washington. Plans are under consideration to increase facilities and to make most satisfactory the conditions surrounding the investigations in marine biology which are in progress. The laboratory will be open during the entire summer season. Professor Frye is now in the east consulting with those interested in the problems under consideration at Friday Harbor.

THE Second Annual Conference of Editors of Agricultural Colleges and Experiment Stations will be held at the State University of Kentucky, June 25 and 26, 1914. Invitations to this conference have been sent to all the agricultural colleges and stations in the United States. Inquiries in regard to the meeting may be forwarded to B. E. Powell, executive secretary of Conferences, Urbana, Illinois.

At a meeting of the Royal Institute of British Architects, Mr. Lionel Earle, permanent secretary of the Office of Works, in the course of discussion on a paper by Mr. W. A. Forsyth on the repair of ancient buildings, mentioned that the treatment of decaying stone due to sulphuric acid in the air had

given his department much anxiety. The matter was of such far-reaching importance that the treasury had granted a sum of money for one, two, or three years to institute a scientific inquiry, and he hoped to obtain the services of Professor Laurie, of the Heriot-Watt College, Edinburgh, to that end. The Foreign Office had also consented to inquire of the governments of France, Germany, Italy, Greece and America whether any treatment had been evolved in these countries to combat this evil.

AN efficiency limitation of quite a different type from that imposed by the inadequate and dangerous quarters occupied by the United States Geological Survey is presented, according to the annual report of the director, recently made to Secretary Lane, in the restrictions placed in one way or another upon the selection of personnel. Under "lump-sum" appropriations there is a fair opportunity to obtain high-grade service in the scientific and technical positions, yet even here the restraining influence of precedent prevents attaching to the higher positions salaries that are more than a fraction of those which the well-trained specialists best fitted for those positions can obtain for similar work in the service of corporations. This condition has resulted in many of the members of the Geological Survey leaving government service at the time when they have become most valuable as public servants. Thus in the four and one half years ending January, 1913, the number of geologists who left the government service for the primary purpose of bettering their financial condition was 41, and these men are known to have received salaries outside of the public service amounting to an average immediate advance of 149 per cent., or practically two and one half times the salaries paid them by the Geological Survey.

THE Euphrates barrage from Hindich north to Bagdad was opened on December 12. It is the portion of the great irrigation works designed by Sir William Willcocks, the designer of the Assouan dam. The system, according to a dispatch from London to the *Boston Transcript*, will cost, when completed, no less

than \$115,000,000, of which \$25,000,000 has already been expended on the present section of the work, known as the Feluja project. Three million acres of what were in early history the finest agricultural lands are to be eventually reclaimed. When the system is completed the Tigris, the Euphrates and the Akkar Kuf Lake will form part of a controlled system of canals, weirs and barrages, whereby the pernicious silt is to be separated, floods are to be prevented, and wheat-bearing land is to be nourished with water. It is estimated that the cultivated area will be doubled, and that the crop of wheat along the Euphrates will be trebled. The scheme would also result in a vast increase in the yield of cotton. It consists of providing a means of escape for the flood waters of the Euphrates along the depressions of the Pison, but it also entails the construction of a great central canal, regulators to control the supply from the Euphrates at the head of the Sakhlawia, a weir on the Tigris, a canal for irrigation to the north of Bagdad, another canal along the right bank of the Tigris, and the building of a railway along the left bank of this canal for the transport of the harvests. Moreover, the construction work would include a railway to connect Bagdad with the Mediterranean by a short and cheap route. The project was submitted by Sir William to the Turkish government in 1909, after a year's study of the situation, a study which he continued through the two years subsequently up to the time of his resignation in July, 1911, as adviser to the Turkish Ministry of Public Works.

UNIVERSITY AND EDUCATIONAL NEWS

WESTERN RESERVE UNIVERSITY will receive from the McBride family of Cleveland a lecture foundation with an endowment of \$50,000.

THE following changes concerning the admission of students to the Johns Hopkins Medical School have been announced. In 1913 the number of students in each class was limited to ninety. In order to receive consideration applications of incoming students must

this year be made by July 1. After that date the various applications will be sifted and an attempt made to choose the most likely ninety applicants. It has also been decided to increase the requirements for admission in chemistry and, in addition to the 150 hours of laboratory work in inorganic chemistry now required, an additional 90 to 100 hours of laboratory work in organic chemistry will be required of all students desiring to enter the school after October, 1914.

BEGINNING next year the two-year courses in the college of agriculture at the Ohio State University will be lengthened to three years. The Tuesday before October 15 is the date set for opening and the Friday before March 15, that for closing. Farmers' sons may, with this change made, come to school after harvest and complete the year's work before the spring work begins on the farm. No attempt to extend the subject matter is intended, and the length of the course is practically the same, but boys from the country may engage in practical farming while taking the agricultural course under the new system.

PLANS are being perfected for the centennial of the first conferring of degrees by the Yale medical school. Special exercises will be held in Woolsey Hall on Monday afternoon of commencement week from 4 to 6, and historical addresses, the conferring of honorary degrees, exhibits and other features will be arranged.

Mr. A. W. McCoy (A.B., A.M., Missouri) instructor in geology at the University of Missouri, has been elected instructor in geology at the University of Oklahoma.

THE General Board of Studies of Cambridge University have appointed Dr. Assheton to be university lecturer in Animal Embryology.

DISCUSSION AND CORRESPONDENCE

REPLY TO A RECENT CRITIQUE OF AN OLD REVIEW IN SCIENCE

IN the current number of the *Bulletin of the American Mathematical Society*, December, 1913, pages 147-151, Professor E. B. Skinner makes erroneous statements regarding my re-

view in SCIENCE¹ of Professor L. W. Reid's "The Elements of the Theory of Algebraic Numbers," and also regarding the history of the subject.

1. In my review I had said:

After stating formally theorem A and devoting fifteen lines to its proof, the author informs us that the "theorem therefore fails." Similarly, on pages 250-251, theorems are formally stated and later shown not to hold in general. This peculiar style of pedagogy is decidedly a novelty to the reviewer.

Quoting only the first sentence and that incorrectly, Professor Skinner insists that the quotation puts the author in a wholly erroneous light. But the entire passage certainly makes clear that I was merely questioning the wisdom of this peculiar style of pedagogy. There was no need whatsoever for any comment in SCIENCE on the bare fact that the author stated a formal theorem in italics, devoted a half page to a "proof," and then indicated that the proof failed and that the "theorem" itself was false, repeating the same process on pages 250-251. I think I was justified in presupposing upon the part of a reader of my review that small degree of acumen which would enable him to conclude unguided that if an author devoted considerable space to a false theorem, the failure of the theorem was regarded by him as of sufficient interest to warrant attention. It is unfortunate that the author and Professor Skinner speak also of general theorems which they nowhere state explicitly and which if stated would be false, except in the very simplest cases, as they well knew.

2. In my list of important topics omitted from the book, I included erroneously that of class number. It occurs first on page 434, just seventeen pages before the end of the book. One may be pardoned for not looking at the end of a long book for a topic which should play a fundamental rôle in the whole theory.

3. The last paragraph of my review has gone through a remarkable metamorphosis in the hands of Professor Skinner. What I actually said was:

¹ SCIENCE, N. S., Vol. XXXIII, pp. 188-89, February 3, 1911.

In the matter of references the author has been particularly unfortunate. In a book barely entering upon the threshold of the theory, a scarcity of references would have been entirely justifiable. But to give hundreds of references to a certain report on the subject (excellent although it be) and to completely ignore the literature and not even mention the names of the discoverers of the theorems is against all scientific traditions.

What Professor Skinner says I said is:

Again, the reviewer, deploring the omission of references, says: But to give [as above].

My second sentence above (not quoted by Professor Skinner) shows that I did not deplore the omission of references. This sentence together with the one actually quoted by him show that what I deplored was misplaced references. As should be well known, Kummer created a highly complex theory of ideal numbers for the case of fields built upon roots of unity; then Dedekind created a simpler theory of ideals in complete generality and developed the subject at great length; then Hurwitz made a simplification which yields a brief and attractive exposition of the theory; also Dirichlet, Kronecker, Hilbert, Minkowski, Hensel and others have contributed to the development of the subject in various directions. A very large proportion of the theorems stated on pages 218-451, the part dealing with quadratic fields other than Gauss's important case, should have been attributed to Dedekind, provided a reference was to be given. But in these 234 pages, I find only four references to Dedekind, once to an alternative proof, once to a symbol, once to a simple lemma, and finally to a wholly subsidiary theorem. There are two references to Minkowski and one to each Woronoj (on cubic number fields), Hurwitz, Sommer, H. J. S. Smith and to Chystal's algebra. The references to the main theorems are to that excellent report by Hilbert, recently translated into French. As against the four wholly minor references to the originator of the general theory, Dedekind, there are 45 references to Hilbert's report (Professor Skinner's count of 38 for the entire book is misleading as he neglected references given in the body of the text). With a single exception, these 5 references are to passages in Hil-

bert's report in which Hilbert expressly attributed the results to other writers; had the author reached the higher parts of the theory, he would have needed many references to Hilbert's own important contributions. On my own part the impression that there were hundreds of such references was wrong; but that exaggeration is really beside the mark. The references are largely misplaced and that is evidently all I was emphasizing in the passage quoted above. I do not begin preparation for writing a book review by counting references, and I do not care a straw whether or not Professor Skinner's count of 158 as the total number of footnote references is correct; in any event only about 44 of these relate to the part under discussion. In the above extract from my review I expressly limited myself to the subject of the report and hence to algebraic numbers; consequently it is not a fair comment on that extract to speak of the large number and nature of the references in the introductory part on rational numbers. In all probability these references would have been like those discussed above had the report treated also rational numbers.

4. Professor Skinner states that my review was freely interspersed with exclamation points. As a matter of actual fact only two exclamation points appear in my two-column review. One is in

The author desires to bring out a closer relation between rational numbers and quadratic numbers. This he accomplishes by complicating the elements of rational numbers with the unnecessary machinery of quadratic numbers! We find on page 91 Wilson's theorem stated in the form

$$r_1 r_2 \dots r_k + 1 \equiv 0 \pmod{p}, \quad k = \phi(p),$$

where r_1, \dots, r_k form a complete set of residues modulo p , a prime.

According to the Index, this is the first statement in the text of Wilson's theorem, which has been known since 1770 under the familiar form that $1 \cdot 2 \cdot 3 \dots (p-1) + 1$ is divisible by the prime p . After the complicated theorem is stated, proved, generalized and illustrated by several examples, the usual form is finally given. The second exclamation point was used in discussing a three-

page proof which could have been given in a few lines.

5. If, in the three years intervening between my review and his attack on it, Professor Skinner had given less time to the counting of footnotes and more time to the comprehension of the passages quoted from my review and to the unquoted context of those passages, he would possibly have saved himself from "careless and inaccurate statements," instead of attributing that term so freely to my review.

6. Professor Skinner makes on page 150 the remarkable statement:

Furthermore, the author has put in a very clear light the historical sequence of the ideas which led to the development of the theory.

On the contrary, the author made no such pedagogical blunder. He wisely did not attempt to give any idea of Kummer's ideal numbers, the operations on which are so delicate that one must use the utmost circumspection (as remarked by Dedekind in his important historical papers in Darboux's *Bulletin*). Nor did the author present the second stage (Dedekind's viewpoints) in the historical development of the theory. For most obvious reasons the author refrained from presenting "the historical sequence of the ideas," and confined himself to the simplified present-day exposition of the theory, as far as he went.

L. E. DICKSON

A REJOINDER TO DR. DAVENPORT

THE task of the critic is always a disagreeable one, and it is only the conviction that the fate of eugenics as a science depends on the repudiation of much of the recent work of the Eugenics Record Office which impels me to reply to Dr. Davenport's letter in *SCIENCE* of November 28. I shall confine myself to the three points he raises regarding the paper on heredity in epilepsy although these points are not in the least representative of my criticism of that paper. Indeed, I dealt with not one, but a whole series of publications in which Dr. Davenport is concerned.

(a) Dr. Davenport states that

First, Dr. Heron seems to assume that whenever a symbol in a pedigree chart is not accompanied on the chart by some special description it stands for a person about whom nothing is known. He calls attention to numerous cases where, notwithstanding, the corresponding individual is described in the text. The assumption is a gross error. The chart shows mainly the interrelationship of individuals, and indicates only certain traits.

Bulletin No. 2 of the Eugenics Record Office¹ is entitled "The Study of Human Heredity" and the opening sentence reads:

The following methods are in use at the Eugenics Record Office. . . .

The "plan of charting" adopted is described in section 2 and it is there stated that while the letters E, F, I, N, etc., placed in or around the square or circle which stand for male or female, indicate that the individual in question is epileptic, feeble-minded, insane or normal, etc., "when no letter accompanies the individual symbol it means that no definite data had been secured at the time the chart was made" (page 4). Further, Plate V. on page 16 is entitled "Key to Heredity Chart" and there examples of the symbols used are given. The first two are the square and circle without any accompanying letters and the description given is "No data." Again, in his tables Dr. Davenport uses a symbol X which he defines as "Unknown" (I pointed out that more than half the individuals entered in the tables were described by Dr. Davenport himself as "unknown"). Now in the great majority of cases the square or circle without any accompanying letter corresponds to an individual marked "unknown" in the tables, but I pointed out several cases where mistakes had been made. To take the first example I gave in my paper, Fig. 10, case 469, the chart shows two sisters one of whom is marked epileptic while the symbol for the other is left blank to indicate that "no definite data had been secured at the time the chart was made" or that there were "no

¹ It was reprinted in Bulletin No. 7 of the Eugenics Record Office, September, 1912.

data." In the description of the pedigree the first sister is stated to be "certainly epileptic," the second merely "shows signs of epilepsy," while in Table I. both are definitely entered as epileptic. Yet these different statements occur in one and the same study of inheritance in epilepsy.

(b) Dr. Davenport writes that,

Second, Dr. Heron catalogues with infinite pains, "errors" in citing the case numbers. Here he has fallen into a trap which the authors unconsciously prepared for him. To avoid the possibility that a person who is not authorized should connect an individual at the institution with his family history it was decided to apply alterations to the case numbers which enable the authors, but not the ordinary reader, to identify the case.

My criticism was summed up as follows:

Tables A, C and D (of Drs. Davenport and Week's paper) thus contain particulars regarding the relatives of 74 normal parents. In only 30 cases do the entries agree with the tables from which they are supposed to have been extracted, or with the pedigrees given in the paper. In 13 cases out of 74 the case numbers do not agree, while 9 cases which ought to have appeared in Tables C and D have been omitted.

The whole of the errors made were definitely cited by me and the following may be given as examples. Case No. 4529 of Table IV. appears as No. 4521 in Table A of the same paper and No. 2124 as No. 2129. Comparing Tables VI. and C we find that No. 335 appears as No. 332, 481 as 483, 504 } b as 503 } b, 1705 as 1704, etc. Yet 8781 } 3781 } b, 1705 as 1704, etc. Yet Dr. Davenport now states that these changes were deliberately made by him to hide the identity of the individuals dealt with. I am quite unable to understand how any individual can be identified as No. 4529 and yet escape identification as No. 4521. Perhaps Dr. Davenport will also explain how a pedigree came to appear in Bulletin No. 4, Table VII. as No. 2983, only to be changed in Table D of the same paper to No. 2984, to reappear at the Eugenics Congress as No. 2983 in Table VII. and to return to No. 2984 in Table C.

(c) Dr. Davenport states that I overlooked the fact that the details of his pedigrees were sometimes entered in 5 columns and sometimes in 9, 10 or 11 columns (not only in 10 as he states). I was well aware of the fact and made no objection to this procedure since in most cases Dr. Davenport has made up the deficiencies of his "5-column" classification by a long series of footnotes. I did object, however—to cite only a single example—when I found in case 2487 that there were four different versions of the mental condition of a single fraternity of 12 children and pointed out that Dr. Davenport gave of those who died early 0 or 2, of the "unknown" 0, 1 or 6, of the insane 0 or 1, of the neurotic 0, 3, 4 or 5, and of the alcoholic 1 or 2, according to the page consulted. It is for Dr. Davenport to justify these differences.

Finally I would ask those who wish to judge between Dr. Davenport and myself to read my memoir in conjunction with those of Dr. Davenport which I have criticized. They will then be able to judge for themselves whether or not my criticisms are justified. They involved far more serious matters than those to which Dr. Davenport now endeavors to reply.

THE FRANCIS GALTON EUGENICS LABORATORY,
UNIVERSITY OF LONDON

SCIENTIFIC BOOKS

Researches in Physical Optics with Especial Reference to the Radiation of Electrons.

Part I. By R. W. Wood. Columbia University Press (New York, 1913). Pp. 133, plates 10.

This volume, whose subtitle serves to illustrate the manner in which the electron is dominating current thought in physics, is the most recent number of the Ernest Kempton Adams Series. Of the eleven papers which are here collected all are experimental in character: a large number of the results have already been announced in other places, mainly in the last three or four volumes of the *Philosophical Magazine*.

In point of importance, the first two of these essays, dealing with the truly remarkable phe-

nomena found in the resonance spectra of iodine vapor—phenomena discovered by the author—ought probably to rank highest. The fundamental fact in regard to resonance spectra, namely, that a vapor when illuminated by monochromatic light which comes from a single direction will become self-luminous and will reemit light of the same wave-length in all directions, would appear to put this phenomenon into a category entirely different from that of ordinary fluorescence and to make it extremely worthy of investigation.

The first paper deals with the advantages which came from the use of iodine vapor in place of sodium vapor, and with the structure of the absorption spectrum of iodine, which with Wood's forty-foot spectrograph shows no less than seven lines within the space occupied by the green mercury line alone. Here also is described the curious and unexplained effect of mixing helium with the iodine vapor, namely, the transformation of resonance spectra into banded spectra. Another unexplained phenomenon in this connection is the fact that when the exciting beam of light is polarized this polarization is passed on to the lines of the resonance spectra.

The second paper describes the 40-foot spectrograph with its now celebrated "pussycat" attachment and also deals with the absorption spectra of iodine and the emission spectrum of mercury. Wood estimates the number of absorption lines in iodine vapor at 50,000, and recommends it as superior to sunlight for testing large gratings. Important extensions of this work on iodine vapor are reported in the current (November) number of the *Philosophical Magazine*.

The third paper deals with the resonance spectrum of another vapor—that of mercury—which is excited only by ultra-violet light of wave-length 2536. Here is related the discovery of "secondary" resonance, a remarkable radiation, which comes, not from the vapor directly illuminated by the exciting ray, but from those portions of the vapor which are illuminated only by primary resonance radiation. A most interesting feature of this paper

is the experimental passage from diffuse to regular reflection of resonating vapor, *i. e.*, from volume to surface reflection. Experiments show that the resonance radiation "begins to weaken at a pressure of about 2 cm. (mercury vapor) and is practically gone at 70 cm."

Next follows a not very successful attempt to determine the anomalous dispersion of mercury vapor in the neighborhood of λ 2536, by use of Puccianti's method. Among the most interesting results in these papers must be reckoned those in which Professor Wood has determined, by experiment, the connection between transparency of a layer of metallic globules and the diameter of those spheres. Using a layer of mercury droplets deposited as "dew" on a quartz plate and examining them for transparency by use of infra-red rays of wave-length 112μ he finds that these metallic particles have no effect in stopping long heat waves until their diameter begins to exceed one tenth of a wave-length. Very striking also is the fact that such a sheet of small metallic particles—packed together in such a way that they almost touch—seems not at all to interfere with the transparency of those portions of the plate not covered by the metal; the plate remains as transparent for waves of 112μ as for waves of 1μ .

Paper No. 6, dealing with diffraction gratings having a controlled groove-form, does not quite reach the level of those which precede it. The next contribution contains some excellent photographic examples of the reflective power of nickel films on glass and numerous details concerning the author's method of depositing these films.

Paper No. 8 carries the title of "Selective Absorption of Light on the Moon's Surface and Lunar Petrography," the latter half of which impresses one as rather ambitious. "Petrography" is a word which has too definite a meaning to be employed as a description of local differences of color either on the moon or on any other body. The method employed is that of using different ray-filters for photographing the moon with light from three regions in the spectrum; and then combining the three negatives into a three-color

picture. The silvering process was evidently described during a moment of relaxation when the author's characteristic humor came to the surface as follows: "Personally I never weigh my nitrate of silver, as I enjoy the element of the personal equation which enters the problem when scales are dispensed with." How seriously this is to be taken may be judged from one or two of his immediately following sentences. "From one to two grams to 100 c.c. of distilled water is about right." "Unfortunately things as described above seldom happen at the first trial." "It troubled me much when my personal equation contained one more variable than at present, but I have not seen it occur recently. As the production of the uniform blue film depends upon getting the proportions just right, I suppose the beginner had better mix measured amounts for each trial unless he has access to a large jar of silver nitrate which 'belongs to the department.'" "The cause of this I do not know. Probably it is osmotic or perhaps catalytic!"

The results contained in the next paper, entitled, "Note on the electron atmospheres of metals," are capable of a quite different and less significant interpretation than that given by the author, as has already been pointed out by several other investigators.

The resolution of the four principal mercury lines, by a five-inch plane grating, ruled by Anderson at Baltimore, is discussed in Paper No. 10, and speaks well for the high quality of the grating.

The eleventh paper concludes the series with an interesting explanation and experimental verification of the "Imprisonment of Radiations by Total Reflection."

Of the volume as a whole, one hardly knows whether to admire more the boldness of ideas which prompt the experiments or the manipulative skill with which they are executed.

HENRY CREW

NORTHWESTERN UNIVERSITY

Astronomy: A Popular Handbook. By HAROLD JACOBY, Rutherford Professor of Astronomy in Columbia University. The Macmillan Company, New York. 1913.

Most astronomers yield at one time or another to the desire to write some popular treatise on astronomy. Professor Jacoby has prepared his volume in the effort "to meet the wishes of the ordinary reader who may desire to inform himself as to the present state of astronomical science, etc." The book is intended also to serve for use in high schools and colleges. To meet this double end, the author has placed all the mathematical notes and explanations in the appendix, where they are at the service of students, while the main body of the text is free from mathematics, which might discourage the "ordinary reader." This method of arrangement is not unusual, but the author has carried it out more systematically than is usually done.

Professor Jacoby's treatment of the subject is distinctly out of the ordinary, and it is this originality of method and style which may well furnish the *raison d'être* for this addition to our astronomical literature. The first chapter is in the form of a general survey of the universe, a prelude to the detailed descriptions which follow. In the third chapter methods are given for finding the planets and stars. This chapter, however interesting for other reasons or valuable for intellectual training, does not impress one as containing the simplest methods for gaining familiarity with the stars and planets. Monthly maps are now published giving the appearance and positions of planets and comets as well as the stars, and it is doubtful if any verbal description, tables and small diagrams can compare in efficiency with such maps in assisting an ordinary reader to the identification of celestial objects. The author, however, would doubtless encourage the use of such maps in connection with the reading of the book. Chapter V. gives a brief but admirable discussion of the sun dial with a description of the manner in which one may be constructed by the reader. The earth and its relationships are handled in an original and interesting way. Under "Moonshine" the author presents the leading facts about our satellite, giving the usual proof of the absence of an atmosphere and the probable cause of its disappearance. No reference is made to the

conclusions of Professor W. H. Pickering, and others, regarding a slight atmosphere and various changes of the lunar surface. The author evidently has little confidence in these observations, since they, if trustworthy, would be of exceptional interest to the "ordinary reader." The different members of the solar system are taken up in order and briefly but clearly described. Probably no other astronomical subject is of such popular interest as the question of the presence of intelligent life on Mars. The author states: "We conclude that neither by visual nor by photographic evidence has the existence of an artificial network of markings been proven, or even rendered highly probable. Therefore the time has not yet come when we shall have to inquire whether geometric lines indicate the presence of intelligent inhabitants: that time will arrive if the lines themselves are ever shown to possess a real or even a highly probable existence." This view is doubtless shared by the great majority of astronomers at the present time.

Throughout the book Professor Jacoby calls attention to the familiar celestial phenomena of life, such as the rising of the sun and moon and their summer and winter paths. In calling attention to such facts and explaining them in a popular manner he has done a real service to the readers of his book. Even among educated people few can answer promptly the question, "Where does the moon rise?", and its changing path during the month and year is either not noticed or regarded as a mystery.

The volume is attractive in form, appears to be free from errors, and is admirably, if not profusely, illustrated. Many lines of recent astronomical advance have been lightly referred to, if at all, but this is inevitable in a popular treatise of such wide scope. The paramount importance of photography in research at the present time might well have been emphasized somewhat more strongly. On the whole, the book is exceptionally well written, and as a popular exposition of the whole field of astronomy is unexcelled.

S. I. BAILEY

ELLIOT'S REVIEW OF THE PRIMATES

For many years the Primates have been in need of systematic revision. The last general work on the order, Forbes's "Handbook," was published in 1894. Study of the group since then, particularly in Berlin, London and Washington, has resulted in a great increase in the number of recognized forms and in the modification of previously accepted views regarding many of those earlier known. In no one of the chief centers of activity is the material extensive enough to form the basis of a general review of the order, and in no two has a common standard of work existed. The resulting confusion was such that the understanding of relationships and the identifying of specimens had become in the larger genera impossible. To remedy these conditions and to establish a foundation for new work are the main objects of Dr. D. G. Elliot's "Review of the Primates."¹ This book is one of the most elaborate monographs ever devoted to a single order of mammals. By its publishing the outlook on the primates has been altered in a way that can be appreciated by those only who have for some time been actively occupied in the study of monkeys. In its 1,351 quarto pages may be found a complete review of the work done in the past by the author himself, his contemporaries and predecessors. It contains descriptions of all the known species drawn up by one person from direct examination of the specimens in all the principal museums of the world. Finally the series of photographs reproduced in 111 of the plates is so well selected and so fine in quality that it might be said almost to exceed in general usefulness the specimens hitherto existing in any one museum.

The inception and plan of the work are thus described by the author (Preface, pp. iii-ix):

1 "A Review of the Primates," by Daniel Giraud Elliot, D.Sc., F.R.S.E., etc. Monographs of the American Museum of Natural History, Vols. 1-3. Three volumes, quarto, with 169 plates (28 colored). New York, published by the American Museum of Natural History (1912), June, 1913. Price, \$30.

"This Review of the Primates is the result of a casual suggestion of my friend Frank M. Chapman, Esq., that I should 'write a book on monkeys.' The magnitude of the task—to compel all the described forms of the Primates to present themselves in their representatives for critical examination and comparison—was thoroughly appreciated, and also it was equally well understood that no institution in the world contained a collection of these animals sufficiently large to permit a work like the present to be completed by its aid alone. . . . Twice were the museums of England and the Continent visited, . . . and during a journey around the world, the museums and gardens of the Far East were also visited and their collections carefully studied. The author has seen and taken a description of nearly all the types of the primates extant in the world today, and there is not a collection of these animals of any importance existing at the present time with which he is not familiar. The results of five years' continuous study are therefore embodied in this work. . . . In the recognition of apparently distinct forms, subspecies in only comparatively few cases have been accepted, because intermediates between what are recorded as species have rarely been found in this order, and neither of two forms, no matter how closely they are evidently related can properly be deemed a subspecies, no intermediates having been observed. Also the author has not seen his way to establish a subspecies between the dweller of an island and one of the mainland, because, no communication being possible, the appearance of intermediates would seem most improbable. . . . In the present work there are altogether fifty-five complete monographs. . . . Each member of the order has been treated after the following method. First a general review is held of the genus accepted, the type fixed and description given; then remarks are made on the appearance and general habits of the species the genus contains, followed by a review of the literature and the geographical distribution, and a key by means of which it is possible that all the species of that particular genus may be recognized. Then each species is taken up in regu-

lar sequence, its synonymy given and the type locality and geographical distribution recorded; the present location of the type, if existing, is then told, after which the peculiar characters of the species, if it possesses any, are given, followed by such remarks as may be necessary upon the relationship the species under review may have with some other in the genus; then a full description and measurements of the type if possible, concluding with an account of the habits so far as they may be unquestionably known. . . . The author can not refrain from calling attention to the illustrations produced by the methods and greatly improved instruments invented by the special photographer of the American Museum, Mr. Abram E. Anderson, which for clearness and perfection of detail, have possibly not been heretofore equalled. Mr. Anderson was sent to London expressly to photograph the crania in the British Museum. . . . The colored illustrations have been selected from those published in the *Proceedings* of the Zoological Society of London. . . . Those of the different species from life were taken by Mr. Lewis Medland, F.Z.S., of London, and certain excellent figures taken by Mr. E. L. Sanborn from animals living in the menagerie of the New York Zoological Society. . . . All the species and races known to the author that have been described prior to June 1, 1912, are included in the three volumes. After the date mentioned, the advanced state of the press work did not permit of any additions, except in an appendix to the third volume."

Following the preface is an introduction of 94 pages, a bibliography of 6 pages, a table of contents, lists of illustrations, list of genera and species in volume 1, and an "errata" calling attention to the single mistake which the author thought necessary to correct. The introduction deals with the general subjects of classification, variation and geographic distribution. There is also a list of the generic names that have been proposed for members of the order, and a complete synopsis of the arrangement adopted: 2 suborders, 8 families,²

² Although the family *Hylobatidae* is very properly used to distinguish the gibbons from the true

55 genera,³ and 588 species and subspecies. Except for the general accounts in the introduction there are no definitions of families and higher groups. There are no keys to the genera, while those provided for the species are not dichotomous.⁴ The account of each species is arranged under the following heads: synonymy, type locality, geographic distribution, general characters, color, and measurements, to which is usually added a discussion of characters and some account of habits. Cranial and dental peculiarities are either ignored or superficially treated; a lack which is partly compensated for by the abundance and excellence of the illustrations.

The nomenclature of the Review is uncompromisingly founded on the law of priority.⁵ The author's cheerful acceptance of the results, anthropoids, the number of such groups recognized is still too small. This is particularly true of the American monkeys, all of which, in spite of their great diversity of structure, are, as usual, crowded into two families.

³ The following generic and subgeneric names are here published for the first time: *Rhinostigma* (I., xl.), type *Cercopithecus hamlyni* Pocock; *Allochocebus* (I., xl.) type *Cercopithecus lhoesti* Sclater; *Neocebus* (I., xl.), type *Simia cephus* Linnaeus; *Insignicebus* (I., xl.), type *Cercopithecus albigularis* Sykes; *Neopithecus* (I., lx.), accidental renaming of *Neocebus*; *Attillemur* (I., lli), type *Cheirogaleus medius* Geoffroy; *Brachyteles* (II., 49), substitute for *Brachyteles* Spix; *Neocebus* (II., 224), included species: *Pithecus resimus*, *P. validus*, *P. alacer*, *P. karimoni* and *P. fuscus* (not *Neocebus* Elliot, I., xl.); *Melanoecebus* (II., 296), included species: *Lasio-pygga leucampyz*, *L. pluto*, *L. nigrigenis*, *L. boutourini*, *L. opisthosticta*, *L. aurora*, *L. stuhlmanni*, *L. neumanni*, *L. doggetti*, *L. princeps*, *L. caruthersi*, *L. nictitans*, *L. n. laglaizi*, *L. sticticeps* and *L. martini*; *Pseudogorilla* (III., 224), type a young male *Gorilla gorilla* supposed to represent the *G. mayema* of Alix and Bouvier.

⁴ There are 17 alternatives beginning with the words "General color" in the key to the species of *Pygathrix* (III., 30-32) and 24 beginning with the word "Hands" in that to the species of *Pithecus* (II., 189-190). Such tabulations of characters can not strictly be regarded as keys.

⁵ Except as regards the formation of names. Here the International code is abandoned and per-

however inconvenient they may temporarily appear, should do much to counteract the present tendency to seek relief in exceptions to the uniform application of this rule. Discussing the name *Simia*, recently shown to apply to the Barbary ape instead of to the orang or chimpanzee, Doctor Elliot says:

"This procedure may be regretted by mammalogists generally, for *Simia* has always been connected with some group of the great apes, but the reasons advanced for doing this were faulty, and an error was committed, and no matter how familiar this act may have become to authors and others generally, yet it was still an error, and therefore something necessary to change and correct. No error can ever become truth simply by toleration and should never be continued when discovered for any reason, and particularly not for the totally insufficient one that the change would inconvenience the memories of certain writers."

The same uncompromising attitude is assumed with regard to every question discussed in the Review: "The conclusions given, no matter how they may disagree at times with the opinions expressed by other laborers in the same field, have in every case been reached only after careful and patient investigation." This strongly personal character of the work is manifest on every page. While it gives the text its chief value it, in connection with the peculiar circumstances under which the manuscript was prepared, accounts also for the main defects. These are the lack of proper correlation between notes made at widely different times and places,⁶ and the generally sonal taste is freely indulged, not always with happy results from the point of view of the purist. For instance, the generic name *Ateles*, evidently intended by Geoffroy as a transliteration of the Greek adjective ἀτέλης, is changed to *Ateleus* (II., 21) with the following comment: "Ἀτέλης (sic a priv. and τέλος (sic), εὖς (sic) a neuter noun, which with the a priv. would be, when Latinized, *Ateleus*."

⁶ At least it is difficult otherwise to explain the frequently-recurring discrepancies such as: the statement on one page that an animal is clove brown and on the next that it is jet black (III., 109, 110); "upperparts bistre" and "upperparts

superficial quality of the descriptions and technical discussions. Nowhere does the author give evidence of felicity in the treatment of those characters of fundamental importance derived from skulls and teeth.⁷ The vital part of a monograph of the order therefore remains unwritten. To an experienced systematist the results of such tendencies can not fail to bring annoyance and disappointment, while to a beginner, or to a person who has no access to large collections of primates, they must render the book often confusing and misleading. The frequent inaccuracy of statement by which the text is marred⁸ will be a further source of black or nearly so" in two paragraphs of a description based on a single specimen (II, 200); "no skull" as part of a color description (III, 70); the application of the same new subgeneric name to two different groups (II, 224, 319); the application of two new names to one group (I, xl, lx, and II, 319); the listing of the name *Pavianus* under Lemuroidea (I, xxviii.), and again under *Anthropoidea* (I, xxxii.).

⁷ The striking peculiarities of the skulls and tooth cusps in the lemurs are barely mentioned; the equally interesting molars of the American monkeys receive no more attention (the remarkably primitive structure shown by those of *Alouatta* is not even alluded to); the molars of the three genera, *Pongo*, *Gorilla* and *Pan*, the cusps of which furnish unmistakable generic characters, are described in practically identical terms; the skull of an ordinary immature male gorilla (the age clearly indicated by the open sutures shown in the photographs) is made the type of a new genus "*Pseudogorilla*" (III, 224), supposed to be intermediate between *Gorilla* and *Pan*. Cranial characters are described for none of the 8 subgenera and for only 3 of the 84 species and subspecies of the genus *Lasiopyga*, though in the preliminary discussion of the monkeys of this group the remark is made that: "Cranial characters . . . are of supreme importance in the discrimination of species . . ." and also that they furnish "one of the most important methods of determining species" (II, 290).

⁸ The following examples have been found during actual use of the book, and without search for errors as such: *Tarsius philippinensis* for *T. philippensis* (I, 9, 10, 12, 13); *Nycticebus menagensis* Lydekker, *Zool. Rec.*, etc., for *Lemur menagensis* Lydekker, etc. (I, 32); I. Geoffroy, Cat.

difficulty to every one who attempts to use the Review in any serious work.

In these initial numbers of its series of "Monographs" the American Museum of Natural History has established a high standard of excellence in book-making. Good paper, clear type and unsurpassed half-tone plates are its main characteristics. Consistent italicization of generic and specific names would have made the text more easy to use, one series of numbers instead of four would have made the plates less perplexing to cite, while "editing" might have been expected to eliminate an allusion to the opossum as a member of the order Carnivora (I, xxi.), together with such solecisms as "crataerrhine and platarrhine" (I, xxi.), and the almost uniform incorrectness in the printing of Greek.

GERRIT S. MILLER

NOTES ON METEOROLOGY AND CLIMATOLOGY

DYNAMIC PRESSURE UNITS

BEGINNING January 1, 1914, the Blue Hill Meteorological Observatory will use dynamic units of pressure instead of millimeters of Primes, p. 51," cited as authority for alteration of *Brachyteles* to *Brachyteles* (II, 49) though the change is not mentioned by Geoffroy. (It is apparently published for the first time by Elliot); *Cynocephalus niger* Desm., Mamm., etc., for *Cynocephalus niger* Desm., Mamm., etc., (II, 162); *Cercopithecus mona* Hollister for *Lasiopyga mona* Hollister (II, 350); description of color of *Pygathrix melanolopha* beginning: "Long black hairs along the forehead, golden cream yellow" (III, 33); original reference to the name *Presbytes batuanus* given as "*Presbytis batuanus* (!) . . . p. 470" (III, 44) when it was actually published on p. 65 and with the masculine form of the generic name; *Pygathrix femoralis* (III, 45), Horsfield cited as authority, though first description was published by Martin, type locality said to be "Tenasserim, Banksun, (Thomas)" though Thomas merely recorded a specimen from Banksun as "precisely similar" to the type; *Pygathrix obscura* (III, 52), Reid cited as authority though he is said to have published no description; *Callithrix goeldii* Thomas . . . p. 100 for *Midas goeldii* . . . p. 189 (III, 261 and I, 224, not 324 as cited on III, 261).

mercury for barometer readings (760 mm. = 29.92 in. = 1,013,303 dynes = 1,013.3 millibars). Also temperatures will be expressed in absolute centigrade degrees ($273^{\circ}\text{A.} = 32^{\circ}\text{F.}$). Until January 1, 1915, the old units will be retained for comparison with the new. Professor Alexander McAdie, director of the observatory will be glad to help any one wishing to adopt this new pressure scale. These changes were first proposed for adoption in the United States by him in 1908.

In the report for the year ending March 31, 1913, the Meteorological Committee of England announces that the centibar or millibar will be used instead of the inch as far as possible for all barometric measurements. Specimens of daily and weekly weather reports are given with pressures expressed in dynamic pressure units instead of inches of mercury, and with temperatures in absolute centigrade degrees.

RADIATION AND CLOUD GROWTH

In the October *Meteorologische Zeitschrift*² Dr. C. Braak, of Batavia, Java, ascribes to radiation certain peculiar phases in the development of cumulus clouds. His description of the formation of these clouds on a calm day may be stated as follows. When the rising sun has warmed the earth sufficiently to drive local air masses to the condensation level, at first single, then many small cumuli appear which soon cover the whole sky. Here and there larger heads rise out of the rather flat cloud sheet. Soon after reaching their maximum height they disappear. If the cumulus growth continues to the cirrus level (about 10 kilometers altitude) the top flattens out. The lower column melts away and leaves this growing sheet. When through energetic upward movement the cumulus cloud rises to even greater heights, there is no longer a maximum level where the vertical movement stops; the condensed moisture falls out, and in the upper

parts of the cloud the air flows toward all sides, forming gigantic cirrus rays.

Thus there seems to be a division of the atmosphere into two parts as regards cloud building. This has a certain analogy with the division of the atmosphere into troposphere and stratosphere: the former designates the atmosphere to a height where decrease of temperature with altitude ceases, and the latter, the isothermal region of unknown vertical extent above this. According to Messrs. Gold and Humphreys³ this is a radiation effect of the air. Below the stratosphere radiation exceeds absorption and convection balances the loss of heat; while in the stratosphere absorption exceeds radiation so the temperature rises over that of convective equilibrium. If one considers the disappearance of the lower part of the cumulus cloud to be the result of cooling and the continuance and energy of the upper part as the result of warming, the analogy becomes nearly complete. Observations in cumulus clouds over Batavia within the lower few kilometers show that the clouds are colder than the surrounding air at the same level. Radiation may thus have greater importance in cloud processes than is commonly assigned to it.

EXCESSIVE PRECIPITATION

SOME recent heavy rains have brought out the following records of excessive rainfall for short periods.

Period	Amount	Place	Date
24 hours	1,168 mm. ⁴	Baguio, P. I.	July 14-15, 1911
24 hours	544 mm.	Alexandria, La.	June 15-16, 1886
18½ hours	523 mm.	Montell, Tex.	June 28-29, 1913
3 hours	406 mm. ⁴	Concord, Pa.	August 5, 1843
80 minutes	292 mm. ⁴	Campo, Cal.	August 12, 1891
30 minutes	235 mm. ⁴	Guinea, Va.	August 24, 1906
20 minutes	205 mm. ⁴	Curtea-de-Ar- ges, Rou- mania	July 7, 1889
14 minutes	100 mm.	Galveston, Tex.	June 4, 1871
5 minutes	38 mm.	Fort McPherson, Neb.	May 27, 1868
30 seconds	4 mm.	Valdivia, Chile	June 11, 1912

SOME RECENT PUBLICATIONS

DR. NILS EKHOLM in a recent work⁵ makes use of isobaric charts (charts of equal changes of pressure) in addition to the usual isobaric charts. His study of the former indicates that pressure changes are of primary importance, while cyclonic and anticyclonic phenomena are secondary.

A thorough study of the thunderstorm observations in Germany for 1910 has recently appeared.⁶ The thunderstorm observations of 1,570 stations are printed in extenso and summarized in a number of tables. The mean velocity for 979 thunderstorms was 38 kilometers per hour; the extreme velocities were 9 and 95 kilometers per hour. Twenty per cent. of the thunderstorms came in May, forty per cent. in June and twenty per cent. in July. There is a special article on the destructive thunderstorm of May 11, 1910.

The British Rainfall Association under the direction of Dr. H. R. Mill deserves credit for its large 52d volume "British Rainfall, 1912." Part 1 contains three special articles on "The Great Rainstorm of August 25-26, 1912"; "The Wettest Summer in England and Wales," and "The Seathwaite-pattern Rain-gauge." Part 2 is an extensive treatment of the British rainfall data of 1912. Part 3 is a general table of the rainfall observed at 5,272 stations.

The report of the Franco-Swedish sounding-balloon expedition in Lapland 1907, 1908 and 1909 has been published recently. As in middle latitudes, the base of the stratosphere was encountered at a mean elevation of twelve kilometers with temperatures of -50° to -60° C. These temperatures are higher than those at the base of the stratosphere in equatorial regions where records of -80° C. are not uncommon.⁷

⁵ "Das Wetter auf der Nordsee während der erste Hälfte von Juni 1911," Copenhagen, 1913.

⁶ Th. Arendt, "Ergebnisse der Gewitter-Beobachtungen im Jahre 1910," Veröff. d. Kön. Preuss. Met. Inst., No. 266.

⁷ See *Scientific American*, December 6, 1913, p. 432.

The pumping action (suction) of the wind particularly in mountain stations offers a serious obstacle to accurate barometer readings. Mr. G. v. Elsner in a monograph, "Über den Einfluss des Windes auf den Barometerstand an Höhenstationen,"⁸ discusses this at length. As yet no way has been found to eliminate this wind effect.

NOTES

IN recognition of the fact that the Blue Hill Meteorological Observatory is now part of the Division of Geology of Harvard University, the members of that Division visited the Observatory November 8. Professor Alexander McAdie, the new Director, gave an address on "Modern Methods of Frost-fighting."

The Smithsonian Institution is to reopen the Langley Aerodynamical Laboratory, which was closed a few years ago. The first serious contribution from the scientific side of aeronautics is to be found in the work of Langley. His original purpose was not to construct a flying machine, but to determine the laws governing flight. Two wind tunnels are to be made for tests on models. In addition to these experiments, an aircraft field-laboratory is proposed for measurements of stress, moments of inertia, etc., and for the adjustment and repair of several full-scale land and water aeroplanes.

The part which high humidity plays in producing heat stroke was well illustrated in Vienna on August 20, 1913. With the relative humidity around eighty per cent. and temperatures between 20° and 23° C., several suffered from heat prostration.

The council of the Royal Meteorological Society has awarded the Symons Gold Medal to Mr. W. H. Dines, F.R.S., in recognition of the valuable work he has done in connection with meteorological science. The medal will be presented at the annual meeting of the society on January 21, 1914.

WE learn from *Nature* (London) that in November the British Meteorological Service

⁸ Veröff. d. Kön. Preuss. Met. Inst., No. 257.

began to issue comprehensive meteorological charts of the north Atlantic, somewhat similar to those discontinued by the United States Weather Bureau in August.

Dr. Julius Von Hann's first section of the third edition of his "Lehrbuch der Meteorologie" is now for sale by the publisher, C. H. Tauchnitz, of Leipzig, at 3.60 Marks.

SPECIAL ARTICLES

MUTATION IN TOBACCO

ALTHOUGH recent work by Heribert Nilsson¹ and Davis² shows that the sudden changes which were observed in *Oenothera lamarckiana* can be logically and simply explained by assuming a heterozygous parent, one should not conclude that this seriously weakens the general theory of the origin of new types by mutation. Even if the indirect evidence compiled by De Vries were also to be rejected, there remain a considerable number of mutations that have arisen in homozygous material of known ancestry. The truth of this statement is apparent if it is recalled that such a careful investigator as Morgan has witnessed the origin of over 150 such changes in *Drosophila*. Controlled botanical evidence is not as voluminous, though plant geneticists have all observed phenomena that seem best interpreted in this manner. For this reason we hope it is not out of place to describe the origin of a variation that appeared in 1912 in a field of Connecticut shade-grown tobacco, which seems likely to be of very great commercial value.

The variety of tobacco grown under cheese-cloth cover in the Connecticut valley is called Cuban. It was first grown in this country in 1904 from seed which was brought from Cuba the previous year by Mr. William Hazelwood, of New York City. The crop of 1904 was very variable, but Hasslebring³ has shown that

this type of variability is due largely to the poor method of saving seed in Cuba. It is the result of a mixture of seed from various types of plants, for crossing seldom occurs naturally.

Individual plants were selected from the 1904 plot which was grown from Cuban seed, and self-fertilized seed produced by covering the seed head with a Manila paper bag. These individual selections were grown in row tests in 1905 and for succeeding years until 1909. The individual rows grown from self-fertilized plants presented a uniform appearance. Of the earlier types all proved of little commercial value except strain 13. One line known as 13-29 proved superior to all others in the value of the cured leaves. A considerable number of self-fertilized seed plants were saved from this line in 1908 and were used for commercial planting in 1910 at the Windsor Tobacco Growers' Corporation in Bloomfield, giving a crop of uniform appearance, in which no variations of importance were noted. A large quantity of seed was saved from this crop, although individual plants were not selfed, as it seemed very improbable that crossing would take place under the cheese-cloth cover, and even if some crossing took place, it was assumed that it would be between homozygous individuals. The Cuban variety was thus selfed for five generations, and in all probability for a sixth generation, and gave every evidence that it was of a homozygous nature.

In 1912 about one hundred acres, or over a million plants, were grown from the seed of the 1910 crop at the Windsor Tobacco Growers' Corporation. The general appearance of the crop this year was very uniform, but when clearing the field in the fall, one of the workmen was very much surprised to discover that one of the plants he had just cut down was very much taller than the others, and bore a large number of unpicked leaves. This plant was brought to the attention of the plantation manager, Mr. J. B. Stewart, who recognized the possibilities of such a plant. After systematic search two more such plants were discovered. These plants were carefully taken up and carried to the Connecticut Experiment Station greenhouse in New Haven. One of

¹ *Zeitschrift für induktive Abstammungs- und Vererbungslehre*, Band 8, Heft 1 u. 2, 1912.

² *Amer. Nat.*, Vol. 46, 1912.

³ *The Botanical Gazette*, Vol. 53, 1912.

the plants survived, and bore 72 leaves, blossoming about January 1. Considerable seed was saved from both the terminal and lateral inflorescence of this plant.

In 1913 about 5,000 plants were grown from this seed. These plants were true to the new type in all external characters, and differed from the normal Cuban in having a somewhat lighter green shade to the leaves, in an absence of basal suckers (lateral branches), and in a practically indeterminate growth, whereas the normal Cuban variety produces a terminal inflorescence after producing from 16 to 25 leaves on the main stem. Twenty plants were brought to our greenhouse in New Haven; all but eight, however, were injured during transportation. The eight uninjured plants commenced to blossom about the first of November, the range of leaf counts per plant being from 62 to 80, with the greater number around 70. These data show that this tobacco mutant is breeding true, and unless it behaves in a different manner from other mutants, it should breed true in succeeding generations.

The cured leaves are very promising, resembling the normal variety. There is every reason to believe that this new type will prove of commercial value, as the yield per acre is at least fifty per cent. greater than the normal type. It has been named the Stewart Cuban.

The normal Cuban seed which was saved in 1910 was again used for planting in 1913, and over 200 acres, or two and one half million plants, were grown. Although search was made at the Windsor Tobacco Growers' Corporation, which grows over 100 acres, no mutating plants were discovered. Two mutants were found at other plantations where the 1910 Windsor Corporation seed was used, which presented the same habit of producing a large leaf number. Thus, five similar mutants from the same seed have been discovered, though it can not be stated that they did not all come from a single normal plant. The frequency of the appearance of this mutation is at the rate of about one plant in a million.

This mutation must have taken place after fertilization, *i. e.*, after the union of the male and female reproductive cells. If the muta-

tion had taken place in either the male or female cell before fertilization, the mutant would have been a first generation hybrid, and would have given a variable progeny the following season.

Mutations of high leaf number have been observed in tobacco previous to this time. Several years ago a variant with a large leaf number was found in the outdoor Havana type at the farm of Mr. Alsop in Avon, and in 1912 a Havana plant which bore 72 leaves was found at the Olds Brothers' Plantation in Bloomfield. Six similar mutations were found at a Windsor farm, and one at another farm in Bloomfield this last season. It is of interest to know that these mutations occurred in a variety, the Connecticut Havana, which has been grown in Connecticut for a period of over fifty years, and which is very uniform in habit. That it has been observed in different sections and by different growers shows that the same mutation must have taken place several times.

A similar type bearing a large leaf number appeared in Maryland several years ago, and is grown commercially under the name of Maryland Mammoth. The Maryland type was, however, the result of a cross between two Maryland tobacco varieties. The mutations which have occurred in Connecticut can hardly be explained on the basis of the results of a cross.

E. G. BEINHART

CONNECTICUT EXPERIMENT STATION,
NEW HAVEN, CONN.

REAL AND APPARENT NITRIFYING POWERS

In making bacteriological studies of soils one of the leading factors determined is the ability of the bacteria present to convert various forms of nitrogen into the nitrate condition. Comparison of this ability, as existing in different soils, is usually made under definite, more or less standard conditions. This factor is spoken of as the "nitrifying power" or "nitrifying efficiency."

Of recent years the tendency has been to employ the soil to be tested, or a standard soil, as the medium in which the organisms

shall work. An additional supply of nitrogen is usually furnished, either in the form of ammonium sulphate, or some highly nitrogenous, easily decomposed, organic substance, such as cottonseed meal or tankage. Where soil has been employed as the medium, one of three methods of procedure has usually been followed. One method is to add to a definite weight of soil a given amount of nitrogen, incubate and then determine the quantity of nitrate nitrogen present. The amount found, taking no account of the nitrate nitrogen originally present, is regarded as indicating the comparative ability of different soil samples to form nitrate nitrogen from other forms of nitrogen; in other words, its nitrifying power—ability—efficiency. A second method is to make a determination of the amount of nitrate nitrogen present in a corresponding sample at the beginning of the experiment; otherwise proceed as above. The difference between the amount originally present and that found at the final analysis is regarded as the correct factor. By a third method duplicate samples are taken and treated exactly alike with the exception that only one receives an additional supply of nitrogen. After incubation both are analyzed and the difference in the nitrate nitrogen content is regarded as the correct factor for comparison.

Recently, in determining what Stevens and Withers have termed the nitrifying inoculating power of a series of plots that are under study, it became necessary to use a soil relatively high in nitrate nitrogen. Cottonseed meal was employed as the source of nitrogen. In a large number of cases, securing the comparative factor by either of the last two mentioned methods, it was found to be a minus quantity. That is, with the conditions optimum (so far as is known) for nitrification, the amount of nitrate nitrogen found after incubating was much less than originally present in the soil. If ammonium sulphate were substituted for cottonseed meal, as the source of nitrogen, such a condition was never noted. This led to a series of investigations to determine the cause of the minus factors that were secured. There were evi-

dently losses of large quantities of nitrate nitrogen. Was this due to actual losses of total nitrogen or was the nitrate nitrogen merely transformed? To what extent does it occur? What are the conditions influencing the same? These are some of the questions an effort is being made to answer. Certain grave difficulties have thus far prevented a complete solution of the problems involved. However, it is believed that in the near future sufficient data, together with that upon which the statements herein presented are made, will be secured to completely settle the question.

One very interesting fact has been brought to light. This is that at least two of the methods now employed in bacteriological laboratories for determining the relative nitrifying power of soils may give us absolutely no indication of true values. The writer has abundant evidence to show that this is true in the presence of appreciable quantities of nitrate nitrogen when easily decomposed organic substances are employed as the source of nitrogen. Oft-repeated observations show that where from five to twenty-five mg. of NO_3 per 100 gr. soil is present and cottonseed meal added, at the end of seven days absolutely no trace of NO_3 can be found. If examined three weeks later an abundance will be present. According to the last two methods mentioned above, the five to twenty-five mg. NO_3 would be subtracted from that found at the final analysis and the difference taken as the factor indicating the amount formed during incubation. In reality, the amount present reached zero at one time, hence all found at the final analysis must have been formed during incubation, and represents more nearly the correct factor.

In a series of experiments designed for the purpose of determining how much NO_3 would disappear it was found that in five days in the presence of .95 gr. cottonseed meal, as high as thirty-five mg. NO_3 per 100 gr. soil had been lost. With 1.9 gr. cottonseed meal the quantity ran up to fifty-five mg. With higher quantities of cottonseed meal still larger amounts of NO_3 were lost. With

small quantities of cottonseed meal the nitrate nitrogen may begin to accumulate again after ten days' incubation. With larger quantities the time is longer. This fact has probably caused many to overlook the first disappearance.

Just what becomes of the nitrate nitrogen, under such conditions, has not been determined. There are two possibilities. It may be liberated in the elementary form through the process of denitrification. This seems improbable since the soil in the writer's experiments has never been much over an inch in depth and never more than two thirds saturated, hence aeration was good. Another possibility is that it may be assimilated. There is always a very copious growth of soil fungi of various forms when cottonseed meal is applied. In fact, so abundant are the mycelial threads that they bind the soil together in a mass which is rather difficult to disintegrate by the ordinary shaking method. It is highly probable that at least a portion of the nitrate nitrogen is assimilated by this growth. It would seem that it would be very easy to determine the above question; but the volatilization of ammonia where large amounts are being formed, as is always the case in the presence of cottonseed meal, makes it difficult.

It is evident, from what has just been said, that deducting the nitrate nitrogen originally present or that in an incubated check, will not give us correct results under the conditions mentioned above. The more nitrate nitrogen initially present, the less reliable will be our results. These two methods must then be abandoned. Simply taking as the correct factor the amount found at the final analysis will probably approach nearer the truth than any other method now in practise. However, we have no assurance that this gives us an accurate idea of the relative amount formed in different soils. There is absolutely no way of determining the actual amount formed that immediately disappears. We only know that in this method the actual amount present at one time (unless very large amounts were initially present) was zero, and that all

formed at any future date must have been formed during the course of the experiment.

DEPARTMENT OF BOTANY,
UNIVERSITY OF MISSOURI

ON THE APPARENT ABSENCE OF APOGAMY IN
CENOTHERA

In a previous note in SCIENCE¹ I described certain experiments which suggested that *Cenothera* was occasionally apogamous. Three imperfect seeds were obtained from a castrated flower of *O. mut. lata*, suggesting the possibility that a small percentage of the seeds might develop apogamously. Last year (1912) the experiments were carried out more extensively, however, and the results were wholly negative, showing that if apogamy occurs in *O. mut. lata* it must be very rare indeed.

Six *lata* plants were experimented upon, whose history was as follows: one was a mutant appearing in a culture of a race of *O. Lamarckiana* from the Kolosvar Botanical Garden; two were derived from *lata* self-pollinated in the cultures of de Vries; two were mutants occurring in a *rubinervis*-like race obtained from Heribert-Nilsson in Sweden; and one was *O. biennis* mut. *lata* appearing in a race of *O. biennis* from the Madrid Botanical Garden. On these plants over 20 flowers were castrated and covered with bags during the height of the blooming season, from July 22 to August 13, 1912. In addition, a whole branch of one pollen-sterile *lata* plant, containing 20 flowers, was covered with a large bag. No growth of the capsules took place in any case, and not a single seed could be found in any of the capsules. It would appear, therefore, that under these circumstances at least, apogamous development practically never occurs in *lata*, for the number of ovules in the capsules observed must have numbered several thousands. The plants were, moreover, all well nourished.

Similar experiments made with eight flowers belonging to four plants of *O. mut. gigas* also

¹ Gates, R. R., "Apogamy in *Cenothera*," SCIENCE, N. S. 30: 691-694, 1909.

gave wholly negative results, not a single seed developing. This race of *gigas* came from an independent source, having originated, apparently by a mutation, in the Palermo Botanical Garden.² Theoretically, it might have been anticipated that the eggs of these plants, having already the diploid number of chromosomes (14) would be most likely to show a tendency to apogamy, but so far as the evidence goes this does not appear to be the case. The unbalanced chromosome number (15) in *lata* might on the other hand perhaps be expected to predispose megaspores or egg cells of *lata* having this number of chromosomes (assuming that such occur) instead of the reduced number, to degeneration.

Nevertheless, from the observation by Geerts of a megaspore mother cell of *Lamarckiana* containing 28 chromosomes, and from the discovery, by Miss Lutz³ and Stomps,⁴ of triploid mutants containing 21 chromosomes, it seems quite certain that eggs containing 14 chromosomes must occasionally be formed in *Lamarckiana*. Why such cells might not develop embryos occasionally, even if unfertilized, is not clear, and perhaps an extensive series of experiments with *Lamarckiana* and some of its 14-chromosome derivatives may yet show that this type of apogamy sometimes occurs.

In the light of these facts it appears desirable that the experiments of Mrs. Rose Haig-Thomas⁵ on apogamy in *O. biennis* be repeated before the results are accepted as facts.

I may add that I have very recently observed a case of parthenocarp in a race of *O. muricata* L. from eastern Canada grown in my cultures this season. This culture contained only four plants, all alike. Earlier in

⁵ Haig-Thomas, Mrs. Rose, "Note sur la parthénogénèse chez les plantes," *Comptes Rendus, IV^e Conf. Intern. de Génétique*, Paris, 1913, p. 209.

the season normal capsules were produced filled with seeds, but the later capsules (observed November 19) though full size and with normally developed walls, were hollow, containing undeveloped ovules instead of seeds. It seems possible that the drop in temperature at the end of the season may have been sufficient to kill the young embryos shortly after the eggs were fertilized, while the capsule walls, already stimulated by the process of fertilization, continued their development. However, nothing of the kind was observed in any other race.

UNIVERSITY OF LONDON

SOCIETIES AND ACADEMIES

THE AMERICAN PHILOSOPHICAL SOCIETY

ON November 7, before the American Philosophical Society, a paper was read by Professor J. M. Macfarlane on "The Phylogeny of Plants in Relation to their Environment." Recalling the conclusions already published in the centennial volume of the Academy of Natural Sciences, the speaker showed that, of the simplest non-nucleate plants the great majority seem to have had a thermal-water or fresh-water origin. Of the simpler nucleate plants, such as the Desmids, the Protococcoid, Pleurococcoid, Chetophoroid, Cladophoroid and related groups, all or the preponderating number were fresh-water. Even the simplest brown algae like *Lithoderma*, *Pleurocladia* and *Heribaudiella* were now in part or wholly fresh-water, as were the simplest groups of the red algae. An estimation of the genera and species of algae and fungi now living revealed that 3,008 genera and about 28,660 species were fresh-water or land forms, 658 genera and 5,930 species were marine. Interesting data were advanced as to transition or brackish species. The phylogenetic origin of bryophytic, pteridophytic and higher classes from certain fresh-water algae was advocated, while the extreme rarity of any genus of these classes in marine surroundings was emphasized. The speaker, therefore, concluded that marine life was probably derived from a thermal-water and later from a fresh-water source. Though contrary to the whole trend of zoological consideration, he indicated that in an abstract already published he had advocated a like origin in fresh water for animal as for plant life, and a derived distribution of many groups of animals into the sea.

Weiss Electro-Magnets

Made by
Société Genevoise

Weiss Electro-magnets are made in four sizes, and with five different forms of pole-pieces. The winding is close to the ends of the poles, thereby concentrating the field at that point. Water cooling, with copper jackets, is provided, thus doubling the period of continuous use. A micrometer screw is furnished, by the use of which the pole pieces may be adjusted to within 0.1 mm. The magnet is adapted for polarization and other attachments.

Volume VIII. Allen's Commercial Organic Analysis.

CONTENTS. Proteins and Albuminous Principles, By S. B. SCHRYVER; Proteins of Plants, By E. F. ARMSTRONG; Proteins of Milk, By L. L. VAN SLIKE; and Milk Products, By CECIL REVIS and E. R. BOLTON; Milk, By HENRY LEFFMANN; Meat and Meat Products, By W. D. RICHARDSON; Proteins of Digestion, S. B. SCHRYVER; Hemoglobin and its Allies, By J. A. GARDNER and G. A. BUCKMASTER; Fibroids and Artificial Silk, By W. P. DREAPER; Enzymes, By E. F. ARMSTRONG; Albuminoids, By JEROME ALEXANDER. Illustrated. Cloth, \$5.00 Postpaid.

Bloxam's Chemistry.

Inorganic and Organic, with Experiments, 10th Edition by A. G. BLOXAM, F.I.C., and SAMUEL J. LEWIS, Ph.D., B.Sc., Ph.C. London. 10th Edition Revised and Enlarged. A compendious work on chemistry in one volume, encyclopaedic in character. Over 300 Illustrations. 878 Pages. Cloth, \$5.50 Postpaid.

Clowes and Coleman's Quantitative Analysis.

10th Edition, Revised. Adapted for use in the laboratories of schools and colleges. By FRANK CLOWES, Sc.D., Emeritus Professor of Chemistry, University College, Nottingham; and J. BERNARD COLEMAN, A.R.C.S., Dublin. Southwest London Polytechnic. 10th Edition. 133 Illustrations. 565 Pages. Cloth, \$3.50 Postpaid.

Arup's Industrial Organic Analysis.

By PAUL S. ARUP, B.S., A.C.G.I. For Technical and Analytical Chemists and for Students. It bridges the gap between academic and scientific chemistry and industrial chemistry. Illustrated. 12mo. Cloth, \$2.25 Postpaid.

Minot's Modern Problems of Biology

Lectures delivered by the Harvard Exchange Professor with University of Jena. By CHARLES S. MINOT, LL.D., Sc.D., Harvard Medical School; author of Minot's Embryology. Octavo. 53 Illustrations. Cloth, \$1.25 Postpaid.

Lewis and Stohr's Textbook of Histology.

2nd Edition arranged upon an embryological basis. 495 Illustrations, many in colors, a great many being redrawn, and entirely new ones added. By Dr. PHILIP STOHR (Wurzburg) and Dr. F. T. LEWIS (Harvard). Octavo. 539 Pages. Cloth, \$3.00 Postpaid.

Lee's Microtometist's Vade Mecum.

A handbook of modern methods. 7th Edition with important improvements. By ARTHUR BOLLES LEE. Octavo. 526 Pages. Cloth, \$4.00 Postpaid.

Folsom's Entomology.

New Edition with special reference to its biological and economical aspects. By JUSTUS WATSON FOLSOM, Sc.D. (Harvard). University of Illinois. Second Edition, Revised. 4 Plates and 304 other Illustrations. 8vo. 402 pages. Cloth, \$2.25 Postpaid.

Stitt's Practical Bacteriology, Blood-Work and Animal Parasitology.

Includes Bacteriological Keys, Zoological Tables and Explanatory Clinical Notes. 3rd Edition, Revised, Enlarged. 110 Illustrations containing 513 Figures. Flexible cloth, 408 Pages, \$1.50 Postpaid.

P. BLAKISTON'S SON & CO. Publishers
1012 Walnut Street PHILADELPHIA

NEW BOOKS

Animal Communities in Temperate America. By VICTOR E. SHELFORD, Instructor in Zoölogy in the University of Chicago.

This volume by Dr. Shelford presents the principles of field ecology, illustrated by the more widely distributed animal habitats of the eastern half of temperate North America, and the aquatic habitats of a much larger territory. Six chapters deal with general principles.

In several chapters the animal communities of lakes, streams, swamps, forests, prairies, and various soils and topographic situations are considered from the point of view of modern dynamic ecology. A very valuable feature of the book is the three hundred figures of widely distributed animals chosen to represent the chief types of animal communities and their characteristic modes of life.

380 pages, 8vo., cloth; \$3.22 postpaid.

Artificial Parthenogenesis and Fertilization. By JACQUES LOEB, Member of the Rockefeller Institute for Medical Research.

This new work presents the first complete treatment of the subject of artificial parthenogenesis in English. Professor Loeb published four years ago a book in German under the title *Die chemische Entwicklungsregung des tierischen Eies*. Mr. W. O. R. King, of the University of Leeds, England, translated the book into English, and the translation has been revised, enlarged, and brought up to date by Professor Loeb. It gives, as the author says in the preface, an account of the various methods by which unfertilized eggs can be caused to develop by physico-chemical means, and the conclusions which can be drawn from them concerning the mechanism by which the spermatozoon induces development. Since the problem of fertilization is intimately connected with so many different problems of physiology and pathology, the bearing of the facts recorded and discussed in the book goes beyond the special problem indicated by the title.

318 pages, 12mo, cloth; \$2.68 postpaid.

THE AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE THE ATLANTA MEETING

UNDER the presidency of Dr. Edmund B. Wilson, professor of zoology in Columbia University, the sixty-fifth meeting of the American Association for the Advancement of Science, and the twelfth of the "Convocation week" meetings, was held in Atlanta from December 29, 1913, to January 3, 1914.

It seems to be almost impossible to obtain an accurate record of the attendance, chiefly because the members of the affiliated societies do not register. The number actually registered at headquarters was 324 members of the association, 54 members of affiliated societies and 16 delegates. Perhaps the total attendance, based to be sure on estimation, was about 500, a very good number when one remembers that Atlanta is rather out of the beaten track of tourists, but even if the number in attendance was not as great as at some of the previous meetings, and notwithstanding the rainy weather, the admirable arrangements and the enthusiastic reception accorded were more than compensation. With that characteristic hospitality of the south the people of Atlanta extended to the visitors a welcome that will long be remembered.

The following affiliated societies met during the week:

Astronomical and Astrophysical Society of America.
 Botanical Society of America.
 American Association of Economic Entomologists.
 Entomological Society of America.
 American Microscopical Society.
 American Physical Society.
 American Phytopathological Association.
 School Garden Association of America.
 Southern Society for Philosophy and Psychology.

On Monday evening the association formally opened its convention by the general session in Taft Hall of the auditorium-armory building. The meeting was called to order by the retiring president, Dr. Edward C. Pickering, who introduced the president of the meeting, Dr. Edmund B. Wilson. If anything was needed to assure the association of its hearty welcome, surely the letter of greeting sent by Governor Slaton, and the address of Mayor Woodward amply sufficed. After President Wilson's reply, Dr. Pickering delivered the annual address on "The Study of the Stars." This meeting was preceded in a delightful way by an organ recital through the courtesy of the Atlanta Musical Festival Association, Mr. Chas. A. Sheldon, Jr., being the organist. After the meeting the members and visiting ladies were entertained by a reception at the University Club.

On Tuesday from five to seven o'clock the visitors were received by Governor and Mrs. John M. Slaton at the governor's mansion.

Two evening lectures of the popular kind complimentary to the citizens of Atlanta were delivered. On Tuesday Dr. Chas. Wardell Stiles, of the U. S. Public Health Service, discussed "The Health of the Mother in the South," and on the following evening the subject of the lecture by Professor Chas. E. Munroe, of the George Washington University, was "The Explosive Resources of the Confederacy during

the War and Now: A Chapter in Chemical History."

Numerous smokers, luncheons, and dinners and several excursions to near-by institutions and places of historical and scientific interest helped to add to the social pleasure of the week.

The different sections of the association and the affiliated societies met morning and afternoon for the reading of papers throughout the week or until the lists of titles were finished.

The vice-presidential addresses given before the sections were as follows:

Section A: "The Influence of Fourier's Series upon the Development of Mathematics," by Edward B. Van Vleck.

Section B: "The Methods of Science: To What do they Apply?" by Arthur G. Webster.

Section D: "Safety and the Prevention of Waste in Mining and Metallurgical Operations," by J. A. Holmes.

Section E: "Pleistocene History of Missouri River," by J. E. Todd.

Section F: "The Story of Human Lineage," by William A. Loez.

Section G: "The Evolution of a Botanical Problem," by Duncan S. Johnson.

Section I: "The Development of our Foreign Trade," by John Hays Hammond.

Section K: "The Physiological Instruction of Medical Students," by J. J. R. Macleod. (Read by title.)

Section L: "Science, Education and Democracy," by J. McKeen Cattell.

Among the more important actions taken by the Council, the following may be mentioned:

280 members and 200 fellows were elected.

On motion, the following resolutions offered by the committee on policy were adopted:

Resolved, That the council looks with favor upon the organization of a Brazilian division of the association, and that a committee on organization be appointed for this work with Senator Eduardo Braga as chairman.

Resolved, That the Society of American Foresters be formally accepted as an affiliated society.

Resolved, That the council of the American Association for the Advancement of Science authorizes the establishment of local branches of the association in places where the members are prepared to conduct branches which will forward the objects of the association.

Resolved, That the standing committee on organization and membership be instructed to promote the establishment of such local branches.

The associate secretary for the south made an interesting report of the work which he had undertaken towards stimulating an interest in the association in the south. He reported correspondence with several hundred men in southern institutions and a visit to several of the educational institutions of the south.

Dr. McDougal reported news concerning the Pacific Coast Division with reference to the Pacific Coast Meeting. A committee of thirty from this division has been given power to organize for the specific purpose of making preparations for this meeting. He also stated that the Pacific Coast Association of Scientific Societies, composed of three or four hundred members, had also taken this matter up. Members should come prepared to spend at least ten days in California, as meetings would probably be held in three or four different places in the state. The time of holding this meeting was discussed but no definite action taken.

Dr. Pickering and Dr. Holmes on behalf of the committee on expert testimony reported progress, but postponed its final report.

The permanent secretary read a letter from Dr. J. S. Diller, asking that a grant be made for the publication of the twenty-four papers read before Section E, on the Mineral Resources of the Southern States. On motion, a grant of \$200 was appropriated for this purpose.

On motion, the permanent secretary and

the editor of science were instructed to prepare a directory of the funds available for research work for the information of those desiring to make application for the same.

The president announced the members he had appointed on the committee of one hundred on research authorized at the spring meeting of the council.

On motion, a list of the members of the association, the constitution and the official proceedings were ordered printed during the year, and every three years thereafter, provided funds are available.

At the meeting of the general committee, the following officers were elected:

President: Chas. W. Eliot, president emeritus of Harvard University.

Vice-presidents:

Section A: Henry S. White, Vassar College.

Section B: Anthony Zeleny, University of Minnesota.

Section D: Albert Noble, New York.

Section E: U. S. Grant, Northwestern University.

Section F: Frank R. Lillie, University of Chicago.

Section G: G. P. Clinton, Connecticut Agricultural Experiment Station.

Section H: Clark Wissler, American Museum of Natural History.

Section K: R. M. Pearce, University of Pennsylvania.

Section L: Paul H. Hanus, Harvard University.

Section M: L. H. Bailey, Cornell University.

General Secretary: W. A. Worsham, Jr., Athens State College of Agriculture.

Secretary of Council: Henry Skinner, Academy of Sciences, Philadelphia.

Associate Secretary of the South: R. M. Ogden, University of Tennessee.

At this meeting it was decided to hold the next meeting of the association at Philadelphia, during convocation week, 1914-1915.

On motion it was recommended to future general committees that the meeting of 1915-16 be held at Toronto and the meeting

of 1916-17 in New York. It was further recommended that the New York meeting be a special meeting in which all affiliated societies should be invited to take part and that such general convocation-week meetings should be held at intervals of four years, the second to be in Chicago in 1920-1921.

At its last meeting the council passed a resolution extending its warmest appreciation and thanks to the local committee, to the citizens of Atlanta and all those who contributed so ably and willingly to the comfort and entertainment of the members.

Atlanta has been called the metropolis of the "New South" and those visitors who found time to visit some of its many interesting places and institutions went away with new impressions that were not the least assets of a most enjoyable and successful meeting.

H. W. SPRINGSTEEN,
General Secretary.

THE METHODS OF THE PHYSICAL SCIENCES. TO WHAT ARE THEY APPLICABLE?¹

It is generally expected that a retiring vice-president shall deal in his retiring address with one of two things, either some aspects of his own work or some of the important questions which are agitating his own branch of science. My excuse for doing neither of these is that I do not feel that my own researches are of sufficient general interest for mention at this time, and that the masterly address of Professor Millikan last year on the theory of quanta had made it impossible for me to add anything to perhaps the most important of the recent new developments in physical theory. In deciding to content myself with

some general observations I find that I have exposed myself to two risks, one that of repeating ideas that I have before expressed, the other that of seeming to have borrowed from the very interesting and fruitful address of Sir Oliver Lodge at the recent meeting of the British Association.

We physicists may certainly look with satisfaction at the present condition of our science, for although it finds itself in a period of violent flux involving the possibility of the discarding or modifying of some of our most cherished notions, it still remains as the model for the other sciences, many of which it logically includes in itself. When we speak of the methods of physical science, we of course mean the experimental method, as that is what distinguishes modern science from that of antiquity, but we include not only the methods and instruments of observation but also our methods of thought and reasoning. If we are to class sciences by the instruments used, we shall find most of them to belong under physics. Thus astronomy, so long confined to the study of the positions of the stars in two coordinates on the heavenly sphere, made use almost exclusively of the telescope and the clock, as important in the physical laboratory as in the observatory, while the modern part of astronomy annexes to the telescope the spectroscope and the photometer, the bolometer with its attendant galvanometer and the most recent developments of the physical laboratory in measuring radiation, including the recently discovered liberation of electrons from metals by light. For over a century chemistry has depended upon the physical balance as its chief instrument of measurement, while to-day the chemist uses the thermometer and calorimeter, the manometer for gas and osmotic pressures, and all the instruments for the measurement of electrical current and difference of potential that the physical labo-

¹ Address of the vice-president and chairman of Section B—Physics—American Association for the Advancement of Science, Atlanta, December, 1913.

ratory can afford him. As for meteorology or cosmical physics, it has no instruments except those of the physical laboratory.

But even outside of the purely physical sciences, we see the application of their methods of experimentation. In the physiological laboratory we find not only thermometers, but accurate manometers for the measurement of the blood pressure, and registering instruments for all the rhythms of the various organs and the study of fatigue, with electroscopes and galvanometers for the study of the electrical phenomena connected with the nerves and muscles. In fact the fertile brain of the physiologist Einthoven has given back to the physicist the most sensitive galvanometer that he possesses—in the beautiful string-galvanometer which is used to study the action of the heart by means of the electric currents connected with its beating.

The science of botany is one that in many of its methods seems very remote from physics, and the work of the systematic botanist whose main interest seems to be to collect and label different plants and file them away in herbaria seems the antipodes of the methods of the physicist. And yet we have now the subject of plant physiology, in the laboratories of which we see again the familiar physical instruments in new applications. But recently in such a laboratory I saw an artificial tree, constructed of glass tubes and porous porcelain, which raised water from a reservoir and evaporated it into the air in close imitation of a real tree. Here again the thermometer and hygrometer are of prime importance, while we may expect the calorimeter, which has become so very important in physiology in connection with nutrition, to play its part in botany as well. It is of interest to find that the direction of the vertical, which seems to be so important in connection with the growth of plants, is not mysterious, but that if the plant is

subjected to centripetal acceleration in a whirling machine, its root will yield exactly as to gravity. Finally we must credit to botany the study of osmotic pressure, the laws of which as discovered by Pfeffer have opened an enormous field to the physicist and chemist.

Finally invading the domain of the mental sciences, we find in the laboratory of experimental psychology, which may be variously termed physiological psychology or psychophysics, the same physical instrument and new ways of applying them. However color is interpreted to the brain by means of the physical and physiological mechanism of the eye, its physical properties must be definitely determined before any progress can be made. Similarly the sense of hearing can not be examined with definiteness until physical standards of sound are forthcoming. The slight advance made in the study of the sense of smell is probably due to the lack of its specification in chemical or physical terms. And the favorite subject of study in this field, that of the time of transmission of nerve impulses or of the formation of judgments, depends on the most fundamental of physical instruments, the clock.

But it would be tedious, as well as unnecessary, to attempt to enumerate all the instruments that have been contributed to the other sciences by physics. Let us turn to the methods of investigation which have proved characteristic of physical science. The collection of examples of phenomena, and their arrangement in classes, is of course characteristic of all the sciences, of botany or of anthropology as of physics. But the essential idea in classification in physics is the quantitative method, which results in methods of measurement, and the invention of instruments for their performance. After this has become possible, the next step is to formulate a theory, which may be of two kinds, either an ex-

planation of the phenomena by means of simpler and more familiar phenomena, or what is more likely to be possible, a theory which is the mere description of the phenomena mathematically in quantitative terms. For example, perhaps the first natural phenomena to be observed were those connected with the recurrence of day and night, the seasons, and the weather. But how long was it before the simple hypothesis was formed of the rotation of the earth, to say nothing of its orbital motion around the sun! And until clocks were invented no very profound conclusions as to the constancy of the length of the day or year were possible. That the properties of space and time might be discussed by philosophers was to be sure possible, but their results would not carry great weight with the new school of natural philosophers. When Galileo deduced by experiment, and described with mathematical precision, the acceleration of a falling body, he probably contributed more to the physical sciences than all the philosophers who had preceded him.

The investigation of physical phenomena has been a most fertile source of improvement of mathematical methods, but this to me most alluring subject I have no time to develop, having treated it at length elsewhere.¹ Of this the most notable example is Newton's invention of the differential and integral calculus, which has given us probably the most powerful instrument devised by man for making discoveries. Without it no progress could have been made in the examination of continuously varying phenomena. Is nature continuous or not, that is, in the neighborhood of every point of space within a distance no matter how small, are there as many other points as we please, and may a similar statement be made for time? Is matter continuous,

and do all varying quantities vary continuously? This I do not intend to discuss, referring you to Sir Oliver Lodge, who took that for his subject. But whether nature is continuous or not, it is extremely convenient to postulate that it is so. We are thus enabled to describe phenomena by means of differential equations, explaining or describing what happens at any point of space and time in terms of what is happening at the infinitely near ones. This has been then the most important of our ways of thinking about physical phenomena. For upon this we have based the method of dynamics, so auspiciously begun by Galileo and perfected by Newton. Galileo gave us the notion of acceleration, very important for a single body, but Newton completed it by that of force, which enables us to describe the actions of one body on another. Let me point out to you that what Newton did in connection with gravitation was not to explain it in the sense of telling what its cause is, but, as I have stated above, to describe it in exact mathematical terms. But, much more than this, Newton, by his succinct statement of the laws of motion, gave us the possibility of the explanation of a vast number of reconcile phenomena in terms of the more familiar ones of dynamics.

The dynamical method then became the most important of physical methods of explanation. Here mathematics, by some thinkers considered, as Huxley said, to be "that science which knows nothing of observation, nothing of experiment, nothing of induction, nothing of causation," has rendered invaluable services. It is true that mathematics can not turn out more than is put in, but it can transform the data in a wonderful manner. Thus proceeding from Newton's definition of force, it led to the notion of energy, and eventually to the conception of the conservation

¹ Presidential address, American Physical Society, *Physical Review*, 1904.

of energy. To be sure, the notion of energy could not become of universal application until justified by multifarious experiment, and yet this has now come to be a principle in which we have more confidence than any other, not only in physics, but in all the natural sciences. But the principle of energy is not the only generalization of mechanics, nor in fact is it sufficient for the establishment of the equations of mechanics. A more general one is found in the so-called principle of least action, established upon a secure basis by Hamilton. From this principle all that we know of dynamics can be deduced, and by dynamics thus defined all the phenomena of celestial mechanics can be explained, with an accuracy almost beyond belief, the single law of the inverse square sufficing for all heavenly phenomena with an accuracy probably beyond that of our description of anything else in nature.

As one of the triumphs of the dynamical method in the explanation of recondite phenomena must be mentioned Maxwell's theory of the electromagnetic field, leading him to the discovery of the electromagnetic nature of light, and the prediction of electromagnetic waves. But in spite of this and other triumphs, the dynamical method alone was not sufficient in many cases.

Chemistry remained intractable by its means, and all the phenomena involving heat seemed outside its range. But it was at this very point that a powerful addition to the dynamical method came to its aid. As remarked above, the principle of conservation of energy would not have become so entrenched had it not been for its experimental confirmation, especially in the domain of the relations between heat and work, as carried out by Joule. The principle of equivalence, which has since been considered as the first law of thermodynamics, then, extended the dynamical generali-

zation to a far larger field, and explained the disappearance of dynamical energy by its reappearance in the form of heat. But even then certain phenomena remained intractable by dynamical means, such as the well-known phenomena of heat conduction. To turn aside for a moment, the treatment of heat conduction by Fourier furnishes an admirable example of a merely descriptive theory, in which everything is exactly described, but it is of no moment for the theory whether heat is a fluid substance, a form of energy or an agitation of molecules. The laws of flow of heat, although merely descriptive, by analogy led to other great generalizations, notably in connection with the flow of electricity and with magnetism and electrostatics.

The method of analogy, always an attractive but dangerous one, led in connection with heat to a generalization which led to possibilities that dynamics could not furnish. The analogy of the working of water in a mill by falling from a higher to a lower level led Carnot to a conclusion, which though based on an imperfect analogy, led to most important results regarding the possibility of thermal changes. From his statement regarding the efficiency of heat engines, as based upon the fall in temperature of the heat employed, has resulted the second law of thermodynamics, or the principle of entropy, which together with the principle of energy has given us a method of enormous power, which may be indeed extended to those sciences toward which the dynamical method has shown itself as yet powerless. It was to the methods of thermodynamics that chemistry was destined to yield, largely through the efforts of our countryman, Willard Gibbs, and of Helmholtz. The reason for the failure of dynamics alone in chemistry may be stated as follows. The method of dynamics requires the complete specification of a system

in terms of a certain number of variable parameters, in terms of which two energy functions may be formed, one involving both the parameters and their velocities of change, and called kinetic energy, the other the parameters themselves only, and called potential energy. Now since we can not see the atoms or molecules, and do not know how they move, we can not form these energy functions, and hence can not form the differential equations. But by means of the principle of equivalence, we may determine the *sum* of the energies, by allowing them to be transformed into heat, and measuring this in a calorimeter. For this purpose we have the valuable thermochemical material of Julius Thomsen and others. But later other methods were devised of holding chemical reactions in equilibrium, and making them go in either direction reversibly. For instance, a salt, which would dissolve in water or an acid with the emission of heat, could in an electrolytic cell, to which a balancing electromotive force is applied, be dissolved or removed from the solution. By distillation the salt could also be removed from the solution, while the use of the semipermeable diaphragm and the methods of osmotic pressure introduced by van't Hoff furnished a variety of methods for the calculation of the energy involved, and the separation of it into two factors, one analogous to a force and the other to a displacement, leading to the definition of chemical affinities. This necessary step being taken, and Rayleigh and Gibbs having shown how the entropy could be computed, the methods of thermodynamics became applicable, and chemistry came under the domain of mathematical treatment.

During all this time the question had been many times asked whether the second law of thermodynamics and the properties of entropy could not be deduced from purely dynamical principles, so that ther-

modynamics should be brought under the classification of dynamics. To this question a negative answer had always been returned, although Helmholtz had described a certain sort of system for which the law of entropy applied. It was not until the development of a new method in physics, which though using the principles of pure dynamics, went much farther, that this end seemed to be attained. This was the so-called statistical method, which becomes every day more important, and may sooner or later supersede some of our classical methods involving differential equations. The first example of this was afforded by the kinetic theory of gases, in which the properties of a gas were explained by considering it to be instead of a continuous body, an aggregation of a huge number of small similar molecules, moving about with great velocities in all directions, and by their impacts on each other and the sides of the containing vessel causing the pressure. It was at first the custom to treat them as if moving all with a common velocity, the directions being distributed at random, but to Maxwell occurred the happy idea of applying the principles of probability or statistics, the method namely of averaging up the actions of a great number of individuals of which we know little or nothing singly. For instance, we know nothing of the direction or magnitude of the velocity of any particular molecule, nor of the direction joining the line of centers of two colliding molecules, but we may assume, since we know nothing to the contrary, that all velocities and directions are represented, and that there are fewer individuals possessing very large or very small velocities than those having some mean velocity. The only laws of mechanics made use of were that between impacts the velocity of a particle was constant, and that in each impact the momentum and energy

were conserved. The important thing then was the application of the laws of probability, and by this means Maxwell was led to show that in a steady state, that is, one independent of the time, the velocities were distributed according to the so-called law of errors. As this law is so important, permit me to give the familiar example which illustrates the main points of the discussion. Suppose we have a vertical board into which are driven a large number of horizontal pins regularly arranged in symmetrical diagonal lines. If now we allow shot to fall from a funnel above the middle of the board, a shot striking any pin will fall either to the right or the left. Of course the circumstances will, according to the laws of dynamics, determine in each particular case which way it will fall, but if we know nothing more about them we can only assume that it is equally likely to fall either way. The next time it strikes the same thing is the case, and the question arises what will be the effect of a great number of similar causes each equally likely to act one way or the other. The answer is simple. Evidently there will be more shot that will fall directly below than toward either side, and the distribution will be symmetrical on both sides, falling off to nothing at great distances. If we should find that the distribution was unsymmetrical we should immediately infer that there was something unfair about the apparatus, for instance, the pegs were different on one side from the other.

Let me here diverge for a moment to point out that here is a method which is as applicable to biological phenomena as to dynamics, and that by its means the resultant of a large number of causes acting at random may be investigated. The essential of the method is that one of two effects is held to be as likely as the other. If we consider a large number of similar objects,

say beans or shells, measure their length or some characteristic feature, the different values will in general be distributed according to the law of errors. If not, our assumptions as to what is equally likely are not true. This statistical method is of the greatest use in anthropology and in the study of inheritance, now such an important part of biological study. It is true that the biologist may object that this method is a purely mathematical one, and is not borrowed from physics. This I shall not stop to discuss, merely pointing out where the same method is applicable to both physical and biological phenomena.

To return then to the application of statistical methods to dynamics. Besides the law of distribution of velocities, Maxwell was able to show that if molecules of two or more kinds were admitted to the same space then when statistical equilibrium was attained the mean kinetic energy of the different types of molecules would be the same, thus leading to a dynamical explanation of the law of Avogadro, one of the most important of chemical laws. Boltzmann, taking up the subject at this point, pushed the generalization of Maxwell farther, and applied it to individuals each more complicated than the simple molecule, and was able to show how a system not in statistical equilibrium tends to approach that condition. Furthermore, he defines a certain function of the state of distribution which continually tends to increase, thus having the same property as the entropy of a system. Thus for the first time we get an explanation of entropy, which dynamics alone failed to give, by means of statistical dynamics or probability.

Perhaps the most striking triumph of the statistical method has been its application to the theory of radiation from a hot body, which has been successfully worked out in the last decade, through the endeavor

ors of Lord Rayleigh, Wien, and particularly Max Planck. In order to explain the dependence of the distribution of energy in the spectrum upon the temperature of the radiating body Planck was led to consider the emission of energy from a large number of electrical oscillators, which from their power of absorption of energy may be also described as resonators. In order to find the entropy to be associated with these resonators by an application of Boltzmann's definition as a probability, and to define what is equally likely as to the amount of energy possessed by the individual resonators Planck found it necessary to assume that this amount of energy could not vary continuously, but must be an integral multiple of a certain very small amount which has been termed the elementary *quantum* of energy. The results of this quantum hypothesis of the atomic nature of energy has been to send a sort of earthquake shock through some of the foundations of physical theory, and we can not yet judge of the ultimate outcome. These matters were handled so thoroughly by my predecessor that I do not need to do more than mention their importance.

I have thus mentioned as the chief methods of physical investigation the method of pure dynamics, that of thermodynamics and that of the statistical method. I may add the method of which I have given an example, that of simple analogy, without the backing of any definite hypothesis. I have spoken of Carnot's successful use of this plan, also of Ohm's law as the analogy of Fourier's. A further example is found in the case of chemical reaction-velocities. Without making exact dynamical assumptions, in many cases it is sufficient to assume that the velocity of a reaction is proportional, like that of a pendulum moving in a highly resisting medium, to the distance yet to go to reach equilibrium, that is,

to the amount of substance that has not yet reacted. We thus get an approach to completion proportional to an exponential function of the time. This exponential is of so frequent occurrence in all parts of nature that the reason for it is often overlooked and we see amusing instances of its rediscovery. It seems likely that this method of analogy, perhaps in this very example, may be of considerable application in biology. Suppose for instance, a portion of jelly inoculated by a needle with a certain bacillus. If the jelly is physically and chemically homogeneous the colony will grow at such a regular rate and with such a symmetrical form that it seems as if a differential equation could be formed, and the analogy with diffusion is very strong. If we could express biological forces or tendencies as we now can chemical ones there is no doubt that we could make long strides in this direction. What is now the outlook for our other methods applied to biology? Where we have to do with a distinctly physical phenomenon such, for instance, as in the propagation of the pulse-wave through the arteries, we may use the methods of pure dynamics. Or where we have to do with the conduction of the electrical current through the tissues we may use the known laws of electricity. But in connection with most of the phenomena of life we are far from having a sufficiently exact notion of the phenomena to apply dynamical principles. On the other hand, the method of thermodynamics may be of great use. No one, I suppose, doubts that the first law of thermodynamics is applicable to all physiological phenomena, both animal and vegetable. Whether it may be extended to mental phenomena is not so certain, and can not be settled until we are able to measure the amount of energy in mental processes. Certain experiments seem to show that we are near to this, and

yet I fancy that no psychologist will yet undertake to measure the relative amounts of energy involved in the composition of poetry, the translation from Greek or German, or the integration of a differential equation. Whether we believe with Mr. Arthur Balfour that "life and beauty and happiness are not measurable" or not, we are still far from having even proposed any units for their measurement.

The question whether the second law of thermodynamics is applicable to biological processes is an interesting one, and we may hope that it will some time be answered, but at present there seems to be great difficulty in defining entropy in connection with such processes. Until this at least can be done, we seem to be a long way from what seems to be the hope of many biologists to reduce the explanation of life to physics and chemistry. While I suppose that most of us believe, with Professor E. A. Schäfer, as stated in his British Association address of last year, that "the problems of life are essentially problems of matter; we can not conceive of life in the scientific sense as existing apart from matter. The phenomena of life are investigated, and can only be investigated, by the same methods as all other phenomena of matter, and the general results of such investigations tend to show that living beings are governed by laws identical with those which govern inanimate matter," while I say, most of us are willing to go so far, I presume that there are few physicists or chemists who will deny that there is probably some additional element involved in life, or who are willing to follow Professor Schäfer in his statement that "The combination of . . . these elements into a colloidal compound represents the chemical basis of life; and when the chemist succeeds in building up this compound it will without doubt be found to exhibit the

phenomena which we are in the habit of associating with the term 'life.' " For if we can not answer the very direct questions that I have stated above how near are we to the position of certainty indicated by Professor Schäfer's words?

If the methods of dynamics and thermodynamics are not of present application in physiological processes, it is fair to suppose that they are even less so in connection with mental processes. That the statistical method is of value here however may be shown by consulting almost any psychological journal. A recent example is to the point. Many persons have the belief that they can tell when they are being stared at by a person whom they can not see. In order to test this subjects were placed under identical circumstances and an experimenter stared, or did not stare, as determined by the fall of a die, for a certain length of time, after which the subject reported on the result, without being informed of the true state of affairs. The guesses were then averaged, and the correct result having been arrived at in 50.2 per cent. of the trials, it was concluded that nothing more than pure chance had been in operation, and that the belief in the assumed ability is an error. What could be more like the examination of a physical phenomenon, and what more convincing? In the same manner we might examine the question of thought transference in general. The interest which the general public has in such investigations, and the desire that they be connected with physical phenomena, is illustrated by the incident of the publication, a few years ago, by a distinguished naturalist, of an obviously jocular account of "The Astral Camera Club of Alcalde," in which the formation of an actual image on the retina of a cat by thought transference was described with such particularity as to deceive so

many readers that an apology and explanation had to be published. What then shall we say of the attempt to push investigations into phenomena supposed not to originate in the world of matter, but in another world of whose existence we have as yet little knowledge, to put it mildly. Only that not only the general public is profoundly interested in the matter, but that eminent scientists, including astronomers, physicists and chemists of renown, have thought such investigations worth their attention, and have even declared themselves to have obtained results worthy of credence.

But how far are we justified in going in this direction? The objects of investigation in the physical sciences are manifold. In many cases we can control the phenomena to be observed, isolating them from disturbances, controlling the temperature, pressure, and other elements, and making the changes repeat at will. In other cases we can exercise no control, and yet the phenomena repeat themselves with periodic regularity, and can be observed at pleasure, as in the case of astronomical phenomena or the tides. In other cases the phenomena come at unknown times, irregularly, and we can observe them only by being prepared, as in the case of meteorological phenomena and earthquakes. But in all these cases there are definite phenomena, which we agree do exist, and which affect matter so as to be perceptible by instruments. But when we do not know whether phenomena exist or not how shall we investigate them? How easy it is for the layman to say, "We know that electromagnetic waves are transmitted through the ether, which we can not perceive by the senses, why should not waves be emitted by the brain, and be similarly transmitted through the ether?" Why indeed! We may answer him that even if we know nothing more of the ether than

the speed of waves through it we know that extremely well, and that whether or not we know the mechanism of these waves (as I conceive we do) we at least know their differential equations, that is, the mode of their transmission. Moreover we have many instruments which are affected by these waves, whereas no one has ever managed, by means of thought waves, to affect the most sensitive instrument, whether torsion balance, quartz fiber, electrometer or galvanometer. When by taking thought, a mind in this world or the next, shall produce the smallest deflection in an instrument at a distance, then we shall be within the means of physical investigation. But, says the enthusiast, perhaps these waves, being not of physical but of mental origin, may be receivable not by physical, but only by mental apparatus, and may work only directly on the resonators of the brain. Very well, let us begin with the phenomena that we can control. It is easy to emit brain waves, if such there be. The method described above is then applicable. But if we are in the region of seismic mental waves, there is nothing to do but have our mental resonators always in adjustment and attuned. Then will come the difficulty of discriminating between "strays" and real receptions. How great this difficulty is is shown by the almost vanishingly small results of the societies for psychical research, so-called, and by the delusions from which reputable scientists have suffered. We may here mention the investigations on the celebrated Eusapia Paladino, who certainly secured good endorsements in Europe, but when brought here and examined by a committee including psychologists, physicists, and other detectives, was found to be explicable by purely physical hypotheses.

It is beyond my purpose to speak of the relations of science to religion and theol-

ogy, if indeed it has any such relations. But I can not resist recalling the scorn with which, in my boyhood, I remember hearing the minister describe Tyndall's famous proposed "prayer-test." I am free to say that I can not at present see why such a proposal should have created such a storm. If people actually believe in the existence of God, and that in addition he does grant requests addressed to him by persons of suitable character, what could be more suitable for decision by the statistical method than such a simple question? Fortunately times have changed, and the nature of prayer is now supposed to be quite otherwise, and to have its beneficent effect by reaction on the emitter, quite irrespective of its treatment at the receiving station. Nothing is more striking than the varying attitudes of scientists toward the subject of theology and religion, from the simple faith of a Faraday, Maxwell or Kelvin to the quite different attitude of a Tyndal, Huxley, or Haeckel. I take this to be due to the difficulty of defining the meaning of the theological terms, and to hazard the opinion that if we could define them even as well as we can entropy we should be found not to disagree profoundly. If it be true that "the undevout astronomer is mad," it is true because we admit that the chief effect of the pursuit of science is to give us a profound admiration for the workings of nature, together with the conviction that its methods are beautiful, definite and simple, and are capable of being understood by the human mind. If this is to say that they thus show evidence of having been designed by a great intelligence, like the human, but enormously more powerful, very well, but it is at this point that we begin to differ as to the meaning of our terms. The chief thing that the scientist should have learned is the possibility of his being mistaken, and the danger of denying in cases

where he has no evidence. We must therefore conclude that while the methods of physical science have a continually widening field of application, we must advise him who asks the profoundly interesting question, "If a man die, shall he live again," to seek to answer it by other methods, *if he can*.

ARTHUR GORDON WEBSTER

THE TEACHING OF PHYSIOLOGY TO MEDICAL STUDENTS:

IN no way is the relative importance of physiology in the medical curriculum better attested than it is by the designation of "the Institutes of Medicine," under which it still appears in the catalogues of some of the older universities. Originating as a division of anatomy, physiology gradually assumed such importance in the medical curriculum as to necessitate the creation of an independent department, although for long the close relationship of the two subjects was maintained on account of the fact that conclusions regarding function had in large part to be inferred from an accurate knowledge of structure. It is for this reason that the study of the microscopic structure of the tissues was, and in some schools still is, assigned to the physiologist, and it is indeed only within comparatively recent years that there has been anything like a general change in the nature of the practical work which the student must do in his course in physiology.

As it now stands, physiology is generally defined as being the study of the phenomena of living things. "It deals with the process of life." It has nothing to do with the structure or morphology of dead things, although obviously a sound knowledge of this must be acquired before any attempt

¹ Address of the vice-president and chairman of Section K, Physiology and Experimental Medicine, Atlanta, Ga., December, 1913.

can be made to explain the functioning of the parts. Physiology, in short, must concern itself with an application of the known laws of physical and chemical science to the process of living in both plants and animals. It must, for example, endeavor to show whether the facts known to the chemist can be made available to explain the synthesis of the various constituents of plants, and the liberation of energy which follows the ingestion of these foodstuffs in animals; it must ascertain whether the movements of a muscle, the secretion of a gland, the transmission of a nerve impulse, are adequately accounted for by the known laws of physics, or whether there exists in living things some force that entirely alters or entirely obscures the physical process.

As thus defined, the science of physiology is obviously too wide in scope, and its ramifications too diversified, to make possible its inclusion as a subject in the medical curriculum. It must be delimited. For this purpose, the object aimed at is of course a knowledge of the functioning of the human animal, although in gaining this we must constantly endeavor to show, by observations on the lower animals, how the same general laws of function apply throughout the animal world. We must, above all things, treat the subject from a broad scientific point of view, not narrowing it down to a mere study of the complicated mechanism of the higher mammalia, but making it a general study of the essential nature of the life processes. Just in so far as the knowledge of physiology is sound will the practise of the physician be likely to be proficient.

For the medical student, therefore, physiology must serve as the connecting link between his pre-medical scientific studies and the clinical work which is to follow. It must be considered as the center to which the basic sciences converge, and from which

diverge the various subjects that are related to the study of disease.

A knowledge of physics, chemistry and morphological biology constitutes the bed-rock upon which the foundation of medical knowledge, represented by physiology, must be built, and it is only after the foundation is completed that it becomes possible to add the superstructure which is represented by pharmacology, experimental pathology, hygiene and medicine. Physiology bears to medicine much the same relationship that anatomy bears to surgery, for the physiologist of to-day is the physician of to-morrow, just as the anatomist of to-day is the surgeon of to-morrow.

The objects which must be kept in view in framing the course in physiology for medical students may therefore be stated as being: (1) a knowledge of the application of the known laws of physics and chemistry in living things; (2) a knowledge of the behavior of those life processes which can not at present be explained on a physico-chemical basis. To impart such knowledge, we must, in the first place, offer the student ample opportunity for the direct observation of the behavior of living things, so that his knowledge of physiology may rest upon a basis of personal observation rather than upon one of authority. The student must, above all things, be trained to be an investigator of the behavior of living things, and he must be constantly reminded that the observations which he makes on the normal animal are later to serve him as a standard with which to compare the behavior of the disturbed functions in disease. But practical courses alone will not suffice. They must be supplemented by didactic instruction of such a nature as to show the student how the facts which he himself gathers from direct observation can be linked together with one another and with those of other investiga-

tors, so as to form a connected account of the working of living things.

As to the actual pedagogical methods by which we are to fulfill these requirements, it will be convenient to consider, first, the practical, and secondly, the didactic instruction. A thorough training in the methods of accurate observation, as applied to living things, must be the first step in the physiology course, for even granted that the student may have graduated in experimental physics, it will still be necessary for him to become familiar with methods by which to control and simplify the variable and complicated factor that the existence of a living tissue now introduces into his experiment. The experiment in physics is one in which everything is more or less controllable, a result once obtained being readily repeated; whereas in physiology a disturbing element is constantly present, for the physiological properties of the living object, whose movement or other function we are examining, may alter from time to time on account of vital processes over which we may not have any known means of control.

There are, I believe, no physiological experiments more suitable for this preliminary teaching than those on the nerve-muscle preparation of the frog. The actual physiological truths which the student may learn by doing these experiments are certainly not of much importance, at least from the medical standpoint, but the facility in accurate experimentation which he thereby acquires, as well as the ability to use his results for inductively drawing general conclusions, is essential to his further progress.

There is one other feature of these experiments that is of great value from the pedagogical standpoint, namely, the possibility of grading them with regard to complexity. In a few weeks the experiment

may pass from the recording on a stationary drum of the degree of muscular contraction resulting from electric stimuli of varying strengths to the determination of the rate of transmission of an impulse along a nerve. When the student has acquired such technical facility that he can repeatedly obtain the same results in this experiment, he may be considered as competent to proceed with the more complicated experiments necessary to elucidate the fundamental truths of physiology.

The experiments on nerve-muscle being thus largely of a preliminary nature, the time occupied by them should not be unduly prolonged; sixteen sessions of two hours each are certainly adequate.

From such work to the study of the heart-beat in frogs and turtles is a natural step, the experimental technique being much the same, but greater care being demanded in the handling of the object under investigation. But another element now enters into the work, for the conclusions which may be drawn from the experiment come to be of great importance in themselves, and fundamental physiological truths concerning the nature of the heart-beat begin to unfold themselves to the observing student. He begins to feel that he is building up his fund of physiological knowledge at first hand, and he gradually comes to take a real interest in finding out, by consultation with his text-books, to what extent his observations and conclusions conform with those that are generally accepted. To encourage the spirit of independent investigation, and to add interest to the work, it is advisable, after a sufficient number of experiments has been performed, to devote a session or so of the class to a symposium in which the results obtained in the experimental work are collated and their significance discussed. For this purpose, each student should be required to prepare in

essay form a review of his findings, which he may be called upon to read before the class, and which is then discussed by the other students, with the object of bringing out the variations that occur, and of emphasizing the chief conclusions.

The time allowed for these experiments should be about one half of that occupied by the preliminary nerve-muscle work.

The student may now proceed to the experimental work on mammals, beginning with such problems as the control of blood pressure, the mass movement of blood, and other circulatory problems, and then proceeding with those pertaining to the respiratory, digestive, excretory and nervous systems. It is in the conduction of this course that the greatest pedagogic skill is demanded, for the experiments must be most carefully chosen so that their results may bring to light fundamental principles, and so that there may not be unnecessary repetition. The animals employed must be deeply anesthetized, and there must be sufficient competent oversight to make certain that at no stage do any of them show the least signs of consciousness. The animals must of course be killed at the termination of the experiment.

The question is sometimes asked as to whether it is necessary for the efficient training of medical students that they should participate in mammalian experiments. In my judgment, the question is as absurd as if it concerned the practical training of engineers. To drive our locomotives we do not employ men who have merely learned the theory of engine construction; we demand such as have gradually acquired a practical knowledge by actual experience.

It is obviously unnecessary that every student of the class should perform each experiment by himself; groups, composed of four or five students, should be formed,

care being taken that the particular duties of the various members are so controlled by rotation that each has an opportunity during the course of actually taking part in every technical detail of the experiment. There should also be a sufficiency of trained instructors so that there is approximately one of these for every two groups. Conducted in this way, the experiments come to assume in part the nature of demonstrations, but they are of immensely greater value than the older lecture-table demonstration, because each student, by being an active participator in the work, comes to take a very much greater interest in the bearing of the experiment, besides acquiring greater operative and technical facility, which will be invaluable to him in his subsequent clinical work.

There are some persons who would doubt the necessity of even demonstrating any mammalian experiments to medical students. They maintain that it is unnecessary to repeat observations that have already been satisfactorily made and recorded. But if this were true for physiology, it must obviously also be true for physics and chemistry. According to those persons, there could be no value in *any* practical work in the pre-medical sciences, which would mean that the student on entering the wards would be no more familiar with the methods which are at his disposal for the accurate investigation of disease than would be a student of theology or law. When we bear in mind, however, that a patient with a disturbed blood circulation is strictly the same from the pathological standpoint as an anesthetized animal with corresponding conditions produced experimentally, we see how unreasonable such a contention comes to be. Is it better to have the student learn how to control a breakdown in the circulation on the patient or on the anesthetized animal? It is pos-

sible in a comparatively brief period of time to make the student of physiology acquainted with the fundamental conditions which disturb the circulation of the blood, for he creates the disturbance at will; it would take years to show him the same things on patients, because the lesions must be taken at random as the cases present themselves in the clinic.

It has been asserted that the mammalian experiments at least should be merely demonstrated to the students and that they themselves should not be called upon to participate in them. It has been pointed out, for example, that the fact that two loads are of equal weight is no more convincingly demonstrated by one's actually placing the loads on the scale pans of the balance than by seeing this done by another person. But the difference between this and a physiological experiment is very very great, and furnishes the very reason for which the latter should be performed by the student himself. For this difference depends on the fact that we are dealing with living processes that may materially alter the result of the experiment unless they are adequately controlled; to learn how to control them is one of the most important things that the student of medicine can learn. It would go beyond the scope of this article to present other arguments for or against the inclusion of practical work on mammals in the physiology course, but there is one pedagogical criticism that sometimes is made against the experiments that should be taken notice of. This refers to the possibility that the student may lose sight of the object for which the experiment is being performed on account of the attention which he must give in order to overcome the technical difficulties which it involves. This is undoubtedly likely to be the case unless great care is taken to have each ex-

periment preceded by a conference, and, after several have been performed, to have the results reported and discussed in seminars. It is true that it may not be possible for the student immediately to correlate and place their full meaning on the experimental results which he obtains, and for this reason the teacher should as frequently as possible refer to these results in illustration of the principles which he is endeavoring to unfold in the didactic courses. Ultimately, however, the observations which he himself has made come to furnish the mainstay of the student's physiological knowledge, and he uses them as the basis for his further development.

Eight to ten sessions of four hours each are required for the mammalian experiments, after which several sessions are occupied in making accurate observations on the physiological functions of normal men, one student in each group serving in turn as the subject of investigation. In recent years the methods available for studies of this nature have very materially multiplied, indeed have done so to such an extent that several of the fundamental principles of physiology can now be as adequately demonstrated on man as by experiments on the lower animals. This permits of a certain amount of displacement of the experiments on anesthetized animals, an object which, for various reasons, should always be kept in view.

Coming now to the place of the didactic instruction, it may in general be stated that this should be so arranged as to supplement the practical. The lecture and recitation are certainly as indispensable as the practical class, for in them the principles of physiology—the institutes of medicine—must be expounded in logical sequence, and, as has already been stated, the bearing of the experiments which the students themselves have performed must

be clearly explained. It is in the lecture that an enthusiasm for the work may be instilled in the student's mind, and it is important that too much weight be not placed on detail, but that every opportunity be taken to show the application of physiological truths in the practise of medicine. For details the student should be referred to the text-books. It is often stated as an objection to systematic lectures that the students come to depend upon the notes which they succeed in taking during them in preparing for their examinations. To offset this possible tendency, there are two other features of didactic instruction which are of great importance. The one is the recitation or quiz, and the other, the symposium. One recitation should follow every two lectures, and it should be conducted, not by the lecturer himself, but by an assistant, who, although using a general outline of the lectures as his basis for questions, does not keep to that alone, but reviews the subject from his own point of view. It is important that a record be kept of the manner in which the questions are answered by each student, for otherwise it is difficult to hold every member of the class to thorough preparation. Review quizzes covering the larger subdivisions of the subject, such as circulation, respiration, etc., are also of great value.

The symposia constitute a most important feature of the course. Besides the symposia on practical work, which have already been discussed, there should be literary symposia, or journal-club meetings, in which each student in turn is required to read before the class a short paper compiled from the literature on some theme which has been allotted to him by ballot. The themes must be carefully chosen, so as to permit of presentation within the short time which is available for such work, and

so that there is adequate representation in the English and American journals. Some students may be given themes requiring consultation of German or French journals, but in our experience the college training in modern languages is inadequate for their extended use in this way.

A general discussion, by the members of the class and by the instructor, should follow the presentation of each paper, the paper and discussion together occupying twenty minutes, thus permitting three papers to be presented in an hour. It is advantageous so to group the papers that the themes discussed during each symposium are closely related, for by doing so a much greater interest is likely to be aroused than if non-related subjects are presented. To prepare, even for the simplest of themes, a well-balanced and comprehensive review of the literature that shall occupy but ten minutes to present, is certainly by no means an easy task, not alone for beginners, but it is impressed upon the students that the practise which they get in attempting to do it will be invaluable to them when later, as practitioners of medicine, they desire to present papers at medical societies. Appropriate reprints of original articles can be lent from the department library to the students, but besides this they should have free access to such general reviews as the *Index Medicus* or the *Surgeon General's Catalogue*, the use and value of which they thus come to appreciate. In order to stimulate their best efforts, we have found it advantageous to offer to submit the best two or three papers for publication to the editor of the local medical journal. There should not be much difficulty in most large medical centers of finding some editor who would be glad to find room in his journal, at least during the summer months, for the publication of well-written, up-to-date reviews on

current physiological literature. A copy of each theme is placed in the department library, and its merit is taken into consideration in determining the final grade of the student.

Finally, at the very beginning of the physiological course there should be several lectures on general physiology, and at occasional periods during it there should be demonstrations by the instructors of more complicated experiments, which it would be impossible for the students themselves to perform.

Much has been written in recent times regarding the relationship of biochemistry to physiology, some believing that each subject should be assigned, like chemistry and physics, to separate departments, whereas others maintain that since physiology proper is the application of both chemistry and physics to the process of living, it should be taught by one who is more or less versed in both of these contributory sciences. In the present connection, our judgment is somewhat simplified by the fact that the question refers solely to the physiological training of medical students, to whom physiology must be taught because it is to serve as the foundation upon which is to be erected their subsequent knowledge of clinical medicine. It must be taught not in dissociated parts, but as an integrated assemblage of all the facts and observations from which its generalizations are induced. It does not matter very much whether the head of the department of physiology is primarily a chemist or a physicist. He should, however, be sufficiently familiar with both sciences to make it possible for him to teach the principles of physiology from both points of view, leaving detailed and practical instruction to associates who are specially trained in the purely experimental or in the purely chemical aspects of the subject. By such

an arrangement, the professor of physiology in the medical school might be either an experimental or a chemical man, and his chief assistant would be especially qualified in whichever branch he himself was not so. Above all things, however, we believe that the two subjects should be taught together so that their interdependence may be constantly insisted upon.

Optional courses in special subjects, given by various members of the physiological staff, offer an important means for making the students cognizant of the nature of the research work which is going on in the physiological world. Although such courses are likely to be attended by the best students only, the class as a whole will come to realize that the department is alive and up-to-date, and that what they learn in the general course can represent but the very fundamentals of their science. The experience in teaching which the instructors gain by giving these optional courses is a further important reason for giving them. There is a growing opinion, and rightly so, we believe, that the experienced head man in the department should expend his energies in teaching the fundamentals of his science, and that he should delegate to his junior associates the conduction of advanced classes. This does not mean that he himself should not offer some advanced course in a subject in which he is specially interested and proficient, but it does mean that to leave to immature and undeveloped assistants the teaching of the fundamentals of the subject as a whole is pedagogically unsound, and is certain to produce a class of students that are unequally trained, and, besides, have a low estimate of the value of the course.

The object of a course in physiology being to train the student in the exercise of his faculties, rather than to jam his memory full of the accumulated truths that fill its

archives, it is important that he begin under the instruction of one who by experience is able to present the sequence of evidence which leads up to the establishment of even the most elementary truths of his science. If the scientific attitude be acquired at the beginning, the student's mind is prepared for the constant acquisition of new knowledge, which he comes to be able to assimilate with less effort, and with immensely greater profit to himself.

An unfortunate feature of every course is the necessity of examination. The necessity exists for two reasons: 1. To offer a disciplinary method by which each student is compelled to study the subject. 2. To ascertain whether he has mastered his subject sufficiently. It is not the purpose in the present paper to enter in any detail into this much-discussed pedagogical problem. It is certain, however, that in no other respect is the teaching of such a subject as physiology likely to be rendered inefficient and unpractical more than by too much examination. As we have stated before, a record of the general behavior of each student in the quizzes, in the practical courses, and in the symposia, should be kept, so as to serve as the main basis upon which his proficiency is determined, the finer grading being based on a comprehensive final examination, which should be partly oral and partly written in nature. In this final examination opportunity would be offered to sort out those students whose standing, as judged from the class records, is uncertain.

Occasional written "tests" are no doubt of some use in permitting the students to measure their standing, and in supplying them with a motive for reviewing their work. But it is a mistake to offer these tests too frequently, for it makes the student consider the obtaining of high grades as the main aim and object of his studies.

By his success in getting high grades, the crammer, who merely memorizes what he hears or reads, comes to be considered as the really successful student, whereas the thinker who accepts nothing until he understands it is discouraged because he can not keep the pace.

And finally as to the future of the physiological student, how is his fund of knowledge to help him most in becoming an efficient diagnostician and therapist? The answer is by keeping him in constant touch with physiology during the time that he is acquiring his clinical knowledge. To accomplish this is, however, a most difficult problem, for it requires that the teacher of clinical medicine shall himself be well informed in the modern teachings of physiology, a qualification which unfortunately but few of our clinical experts possess, or which they make any effort to acquire. There has no doubt been a great change in the nature of the teaching of clinical medicine during recent years. The old-fashioned empirical dogmatism is gradually giving way to more logical and scientific methods, but even in our best-manned school clinics, there yet remain many who by their attitude towards such a science as physiology and towards the newer methods of refined diagnosis, which depend on the application in bedside work of physiological methods, make it very difficult to realize the above ideal. Naturally enough the unthinking student prefers to be taught cut-and-dry systems of diagnosis and treatment. In his textbooks of medicine, he finds tabulated groupings of symptoms by which he may distinguish one disease from another, and he expects that, having learned how to diagnose, all he has to do is to learn the prescribed treatment for the disease. By learning his medicine in such a manner—and of course it is in such a way that he

learns it when he attends so-called quiz classes in medicine—he is very likely to lose all of his scientific attitude towards the management of disease. He comes to think of diagnosis as being nothing more than an endeavor to find the text-book name for the disease under which the grouping of symptoms which he elicits happens to fall, and he loses sight of the fact that the symptoms are the outcome of disturbed function or functions, and that they may vary very much indeed in different individuals, according to the degree of physiological disturbance which the lesion creates. He becomes a student of symptoms rather than an investigator of the conditions which are their cause. After all, text-books of medicine are intended only as rough guides for the classification of disease, and it is fatal to efficiency in medical training if this fact is not constantly borne home on the student. He must be taught to study and treat each patient as an individual problem, and just as he has learned in the practical course in physiology that the same experimental condition may lead to different reactions in different animals, so must he expect to find among different patients the same want of uniformity in the symptoms which are produced by the same lesion. The student must be constantly reminded that the practise of medicine is in its merest infancy, and that its growth depends almost entirely on the degree to which it will be possible to apply the accurate methods of physiology and experimental medicine to its investigation. In the past, the development of knowledge of the disease of the circulating system, for example, has depended upon the use of the simple methods of auscultation and percussion; at the present it is bound up with the use of the electrocardiogram, the polysphygmogram and the skiagram, and in the future it will un-

doubtedly be largely dependent upon methods which will be born and cradled in the physiological laboratories. Every man trained in the right atmosphere becomes a potential contributor to the advancement of clinical knowledge.

In order to carry out these ideals in the teaching of medicine, it is necessary to provide courses such as experimental pharmacology and so-called experimental medicine, in which the more purely physiological experiment is modified so as to show how its results can be used in the investigation of disease. By giving pharmacology in the third year of the medical course, and experimental medicine in the fourth, the difficulty that the student will disregard the scientific aspect of medical practise is much lessened.

In this discussion it should be pointed out that the term physiology is employed in the broad sense under which it was defined at the outset, that is: it includes the physical, the purely biological and the chemical phenomena of life.

J. J. R. MACLEOD.

WESTERN RESERVE UNIVERSITY

ACCIDENTS IN COAL MINES

THE lack of comparable and accurate statistics of coal-mine accidents in the United States has led the Bureau of Mines to collect such data, and the results of these investigations have been compiled by Mr. F. W. Horton, in Bulletin No. 69, entitled "Coal Mine Accidents in the United States and Foreign Countries," which has just been issued. This report shows that during 1912, 2,360 men were killed in the coal mines in the United States as compared with 2,719 for 1911, and that the fatality rate was lowered from 3.73 in 1911, to 3.15 per 1,000 men employed in 1912. The report contains statistical information concerning the production, the number of men employed and the number of men killed in each state since 1896. From 1896 to 1907 the number of men

killed per 1,000 employed gradually increased with only slight fluctuation; the number killed per 1,000,000 short tons also increased, but the rate fluctuated over a wider range.

During this twelve-year period through 1907, the increase in the death rate was accompanied by an enormous increase in the production of coal. In 1896 the output was 191,986,000 tons, and in 1907 it was 480,363,000 tons, an increase of over 150 per cent. In 1896 each man employed produced 2.64 tons coal per day, whereas in 1907 the daily production of each man was 3.06 tons, an increase of 16 per cent. Since 1907 there has been a marked decrease in the number of fatalities at the coal mines.

This general improvement has been brought about by a combination of causes, the principal one of which has been more efficient and effective mine inspection on the part of the state mining departments and the state mine inspectors throughout the country, supplemented by greater care on the part of both operators and the miners. The investigative and educational work of the Bureau of Mines has kept both the operator and the miner alive to the various dangers connected with coal mining, and has shown what precautions should be taken to avoid these dangers. As a result of these educational features, mining companies are organizing safety committees; providing emergency hospitals, training men in first aid and rescue work, so that in case of a disaster they are equipped to cope with any ordinary accident.

The fatality rates in a number of foreign countries covering a period of ten years, 1901 to 1910 inclusive, are as follows:

Great Britain, 1.36 per 1,000 men employed; Germany, 2.11; France, 1.69; Belgium, 1.02; Japan, 2.92; Austria, 1.04; India, 0.96; New South Wales, 1.74; Nova Scotia, 2.65, while the rate for the United States was 3.74. The low fatality rates in the foreign countries may be accounted for largely by reason of the fact that coal-mine inspection has been in operation much longer than in the United States. In Great Britain the coal mine accident statistics have been collected, published and studied since 1851; France, 1853; Aus-

tria, 1875; Germany, 1852; and Belgium, 1831.

A chronological list of the more disastrous coal-mine accidents in the United States shows that 275 accidents have occurred since 1839, in which five or more men were killed at one time, representing a total of 6,777 fatalities. Of these accidents there were 135 that killed from five to nine men each, a total of 859; eighty-two that killed from ten to twenty-four men each, a total of 1,237; twenty-five that killed from twenty-five to forty-nine men each, a total of 870; eighteen that killed from fifty to ninety-nine men each, a total of 1,221; eleven that killed from 100 to 199 men each, a total of 1,534; three that killed from 200 to 299 men each, a total of 695, and one that killed 361 men.

Of these larger disasters gas and coal-dust explosions caused 183 accidents and 5,111 deaths, or over three fourths of the total number of men killed. The next greatest number of deaths were from mine fires, which caused the loss of 1,082 lives, or over fifteen per cent. of the total number killed, by thirty-three separate accidents. It may thus be seen that accidents from gas and coal-dust explosions and mine fires account for more than ninety per cent. of the total number of men killed in these large accidents, although falls of roof, pillars and walls claim nearly fifty per cent. of the total fatalities.

THE RADIUM RESOURCES OF THE UNITED STATES

SECRETARY LANE proposes to withdraw all lands of the public domain suspected of containing radium, that their deposits may be secured for the public good and not become the subject of private speculation. Mr. Lane has outlined his plan in a letter to Chairman Foster of the House Mines Committee, urging immediate passage of a joint congressional resolution to empower President Wilson to make the withdrawals. Investigations of the Geological Survey have located public lands believed to contain the substance now so invaluable in medicine. By the terms of the proposed resolution the Secretary of the In-

terior would be authorized "to conduct explorations and researches with a view to determining the practicability of developing from such ores a supply of radium and to provide for the mining and treatment of radium-bearing ores in such manner as would best secure a supply of radium for the use of the government of the United States and the hospitals of this country."

Secretary Lane points out that there are only two grams of radium at present in the United States. It is valued at \$120,000 a gram. All has been procured from Europe. "Three fourths of the radium produced in the world during the year 1912," says Secretary Lane, "came from American ores, yet we have, up to this time, taken no steps whatever to preserve for our own people this invaluable metal, and our physicians and hospitals are dependent upon European laboratories for such supply as they can procure, and are subject to whatever monopoly charge the European laboratories demand for their product."

In view of the use of radium in the treatment of cancer and the difficulty now experienced in obtaining a supply of it, Secretary Lane says, that as one person in every ten in this country more than fifty years of age suffers from cancer, "it is difficult to overestimate the necessity of securing immediately as large a supply as possible of this mysterious remedy." Continuing, the secretary says: "Radium is found in ores carrying uranium and vanadium, which are used extensively in the arts, and processes by which it is extracted are secret. A process has been invented by the chemists in our Bureau of Mines which promises, from the laboratory experiments thus far made, to be successful. Under the endowment of two Americans, a building is now being erected in Denver (which, with its equipment, will be opened for work in the coming February), in which an effort will be made to prove the commercial possibility of this American process. If successful, this process will be given to the world, and all of the radium secured over and above a small minimum will be the property of the United States, and will be put into the hands of the

United States Public Health Service for public use. Under all these circumstances it seems to me that the only prudent course that the United States can follow is to withdraw such of its lands as are supposed to contain radium from public entry. This will guard against these lands being taken up by those who would not put them to their highest and most beneficial use. It would be inhuman to deprive other nations of access to our radium deposits if they alone were masters of the secret by which this mineral could be secured, and it is believed that there is a sufficient amount of carnotite and pitchblend already in private ownership in this country to permit of continued European experimentation and production. The people of the United States, however, should be entitled to protection against the exhaustion of this resource and its exclusive control by the scientists of other lands."

SCIENTIFIC NOTES AND NEWS

It is proposed to place a suitable memorial of the late Alfred Russel Wallace in Westminster Abbey. It is also proposed to present a statue or bust to the British Museum of Natural History and a portrait to the Royal Society. Contributions to the Alfred Russel Wallace Memorial Fund may be sent to the Union of London and Smith Bank, Holborn Circus, London, E. C.

LORD RAYLEIGH will unveil a tablet to the memory of Lord Lister at King's College, London, on January 14. The ceremony will be followed by the inaugural lecture of the newly appointed professor of physics, Professor O. W. Richardson, F.R.S., recently of Princeton University, who will take as his subject "The Discharge of Electricity from Hot Bodies." Lord Rayleigh will also preside at this lecture.

SIR ARCHIBALD GEIKIE, the distinguished British geologist, has been appointed a member of the Order of Merit, filling the vacancy caused by the death of Alfred Russel Wallace.

OTHER New Year's honors in Great Britain include a viscounty conferred on Mr. James

Bryce, recently British ambassador at Washington.

THE National Geographical Society has awarded a medal in honor of the late Professor Franklin Hiram King for his work on Chinese agriculture.

COLONEL GORGAS, M.D., chief sanitary officer of the Panama Canal, has been elected an honorary fellow of the Royal Sanitary Institute, London.

THE executive committee of the board of trustees of Cornell University has made the following expression of its feeling with respect to the resignation of Professor J. H. Comstock:

In accepting the foregoing resignation the trustees congratulate Professor Comstock on his long, honorable and fruitful service to Cornell University, with which as student and teacher he has been associated almost without interruption since he matriculated as a freshman, and they bear grateful testimony to his success in teaching and in inspiring students and also in scientific investigation, for the continuance of which they trust his health and energy may be preserved for many years to come to the honor of his alma mater and the advancement of truth and knowledge.

After accepting the resignation of Professor Charles DeGarmo, the committee adopted the following minute:

Dr. DeGarmo came to Cornell after twenty-five years' labor as teacher and administrator in school, college and university. Under his guidance the department of education was reorganized and has been a large factor in the preparation of many students for usefulness. During his years of service to Cornell he has wielded a widespread influence in the country through his writings, his addresses to gatherings of school men, his helpfulness to those charged with school administration. In the university he has inspired others by his teaching and even more by the gentle nobility of his character, and by his steadfast devotion to the highest standards of life and work.

PROFESSOR SIMONIN, of the Paris Observatory, Professor Abraham, of the University of Paris, and Captain Carrier, of the French army, the three savants cooperating with a similar party of Americans in determining, with the assistance of radio signals, the differ-

ence of longitude between Washington and Paris, recently delivered short addresses before an audience comprising the Naval Observatory staff and representatives drawn from the naval and scientific circles of Washington.

At the annual meeting of the American Ornithologists' Union in November last it was decided to increase the membership of the Committee on Classification and Nomenclature from seven to eleven with the object of having it organize as two subcommittees, one of four members to consider matters of nomenclature, the other of seven members, to cover systematic and geographic questions, especially the acceptance or rejection of proposed new forms. The president, Dr. Frank M. Chapman, has reappointed the old committee, consisting of J. A. Allen, William Brewster, Jonathan Dwight, Jr., C. Hart Merriam, Charles W. Richmond, Robert Ridgway and Witmer Stone; and as the four additional members he has named Joseph Grinnell, E. W. Nelson, Harry C. Oberholser and T. S. Palmer.

MR. G. W. LAMPLUGH, F.R.S., has been promoted to be assistant director of the Geological Survey of Great Britain, and Mr. T. C. Cantrill to be district geologist.

W. S. VALIANT, for twenty years assistant in the geological museum of Rutgers College, has been appointed curator. Professor J. Volney Lewis, formerly designated curator, has been made director.

THE autumn series of public lectures, given at Washington University, St. Louis, came to a close with an address by Dr. Eugene L. Opie on "Modern Tendencies in Medicine."

THE Friday evening meetings of the Royal Institution, London, will be resumed on January 23, when Sir James Dewar will speak on the coming of age of the vacuum flask. Among the lectures announced is one on the mechanics of muscular effort, by Mr. H. S. Hele-Shaw, F.R.S., and another on the production of neon and helium by electric discharge, by Professor Norman Collie, F.R.S. On February 20 Professor Arthur Keith, conservator of the Museum of the Royal College of Surgeons of England, will relate the results of an

anthropological study of the busts and portraits of Shakespeare and Burns.

THE library of the late Professor Ernest Ziegler, formerly professor of pathology at the University of Freiburg, purchased for the University of Pittsburgh by Mr. Richard Beatty Mellen was formally presented to the university at a meeting held in the University Club, Pittsburgh, December 5. The addresses of the evening were given by Dr. William H. Welch, Baltimore, and Mr. Harrison W. Carver, Pittsburgh.

DR. S. WEIR MITCHELL, distinguished as a man of science, as a man of letters and as a physician, died at his home in Philadelphia, on January 7, at the age of nearly eighty-four years.

DR. SETH CARLO CHANDLER, the distinguished astronomer, at one time assistant to Dr. B. A. Gould, aid in the U. S. Coast Survey and in the Harvard College Observatory, since 1885 engaged in private investigation, died on January 31, at the age of sixty-seven years.

DR. FREDERICK CARL BUSCH, for some years professor of physiology at the University of Buffalo, recently engaged in cancer research, died from that disease on January 3, aged forty years.

HIRAM JOHN MESSENGER, Ph.D. (Cornell), for the last fifteen years the actuary of the Travelers Insurance Company, at one time associate professor of mathematics in New York University, author of publications on social statistics, died at his home in Hartford, Conn., on December 15.

By the will of the late Mr. Arnold Friedlander, an English merchant, \$25,000 is left for a cancer research fund.

THE Ecuadorean government has approved the contract with a London firm for the sanitation of Guayaquil. The question of cleaning up Guayaquil has been under consideration for a long time. Bubonic plague and yellow fever have been prevalent there, and the proper sanitation of the port was made the subject of an investigation by Colonel

William C. Gorgas, head of the sanitary work in the Panama Canal zone. The installation of a proper sanitary system has been made imperative by the early opening of the Panama Canal. It is understood that the cost of the work will approximate \$10,000,000.

UNIVERSITY AND EDUCATIONAL NEWS

THE movement for the establishment of a national university in Washington on the plan indorsed by the National Association of State Universities is taking form, and President James, of the University of Illinois, has, it is understood, commenced the preparation of a bill soon to be submitted to President Wilson for his approval and afterwards to be introduced in both houses of Congress. The bill will carry a preliminary appropriation of \$500,000 toward the establishment of a university to be under the control of a board appointed by the president of the United States. It will propose an advisory board made up of one delegate from each state to frame the policy of the institution.

THE will of the late Seth K. Sweetser, of Brookline, Mass., makes public bequests amounting to \$137,000, including \$25,000 to the Massachusetts Institute of Technology.

ANNOUNCEMENT is made that the Cleveland City Hospital and the school of medicine of Western Reserve University are to be affiliated. The agreement which will be entered into by the city and the university will provide that all members of the visiting staff of the City Hospital shall be nominated by the trustees of Western Reserve University upon recommendation by the faculty of the school of medicine. The visiting staff will have absolute authority over the professional treatment of all patients of the hospital. The director of public welfare will be the administrative head of the hospital. The university will have all teaching and research privileges.

TWELVE colleges, hospitals and charitable institutions of Minnesota, nine of them in Minneapolis, are the recipients of New Year's gifts aggregating \$230,000 from David D. Stewart, of St. Albans, Me., who inherited the

estate of the late Levi M. Stewart, of Minneapolis. Mr. Stewart in the last year has given away \$630,000, practically half of the estate that was left him. About \$400,000 went to churches, colleges and charitable institutions in Maine.

By the action of a New Haven court Yale University is adjudged not entitled to a legacy of \$700,000. The money was devised by Mrs. Henry O. Hotchkiss, who died last year. The court rules that the will is void because Mrs. Hotchkiss did not get for herself complete and ultimate control of the money.

DR. JOHN HUSTON FINLEY was installed president of the University of the State of New York and commissioner of education on January 2. The inaugural address by Dr. Finley was given in the afternoon session. Other speakers included St. Clair McKelway, chancellor of the university; Nicholas Murray Butler, president of Columbia University, and Calvin N. Kendall, commissioner of education of New Jersey. The program for the evening included addresses by Governor Glynn, Franklin K. Lane, secretary of the interior; Charles W. Eliot, president emeritus of Harvard University, and Jean J. Jusserand, ambassador from France.

THE American Political Science Association at its Washington meeting last week adopted a resolution providing for the appointment of a committee of three "to examine and report upon the present situation in American educational institutions as to liberty of thought, freedom of speech and security of tenure for teachers of political science." The committee was authorized to cooperate with similar bodies of other societies of the social sciences.

THE examiners for the Shaw Fellowship open to graduates in philosophy of the four Scottish universities have recommended that it be awarded to Mr. G. A. Johnston, of Glasgow. It is of the annual value of about £160, and is tenable for five years.

MR. A. E. MORTIMER-WOOLF has been appointed demonstrator in the department of anatomy at King's College, London.

MR. GEORGE SENTER, D.Sc. (Lond.), Ph.D. (Leipzig), reader in chemistry in the University of London and lecturer in chemistry at St. Mary's Medical School, has been appointed head of the department of chemistry at Birkbeck College, London, in succession to Dr. Alexander McKenzie, who has been elected to the chair of chemistry at University College, Dundee (University of St. Andrews).

DISCUSSION AND CORRESPONDENCE

A MODERN TEXT-BOOK OF GEOLOGY—AND EVOLUTION

TIME, after all, is a matter of relativity for most of us. To-day, under circumstances, may really be yesterday. A little scientific book of the time of the middle of last century—a few years, say, after the publication of Darwin's "Origin"—has just come under my eyes. But it could not have come much before because its title page bears the imprint, "Quebec, 1913."

It is a little text-book (in French) of geology: "Abrégé de Géologie, par L'Abbe V.-A. Huard, A.M., Directeur du Naturaliste Canadien, Conservateur du Musée de l'Instruction Publique, et Entomologiste officiel de la Province de Quebec."

It is one of a series of similar books by the same author (zoology, botany, mineralogy, geology) which form a "Cours abrégé d'histoire naturelle, à l'usage des maisons d'éducation." It is, in other words, an introduction and guide to science for the rising generation of French Canadians.

It comprises six chapters about the earth's crust, the agents that modify it and the fossils that lie in it; and a seventh divided into two articles: "Art. 1, L'histoire primitive du genre humain; Art. 2, Ce qu'il faut penser du transformisme." It is this last chapter particularly that seizes one's attention.

The first paragraph of the first article concerns the "age of the human species." It is as follows:

"The infallible authority of the Church—[have I neglected to mention that the reverse—

of the title-page of this text-book for secondary schools bears the imprint, "*Nihil obstat*," followed by the signature of the "*censor designatus*" and the *imprimatur* of the bishop administrator of Quebec?—the infallible authority of the Church has made no definite determination as to the date when God created man, nor, by consequence, when man commenced to exist upon earth. There is a chronology in the Holy Books written under the inspiration of God, but in addition to the fact that it must be admitted that in the work of the ancient copyists extending over long periods of time the figures of this Biblical chronology may have been considerably altered, we may believe also that the sacred writer has not pretended to any completeness of genealogy of the patriarchs. Thus from the evidence of Revelation there is no absolute statement to be made relative to the existence of man on the earth; moreover, this is a question that interests neither dogma nor morals."

In two succeeding paragraphs the teacher states that geological evidence shows that man did not exist in the Tertiary epoch. The geological indications are that the creation of man dates from the end of the first period of the Quaternary. "One may add that there is to-day a tendency to believe that the human species has existed for 9,000 or 10,000 years; but this is only an opinion more or less probable that each is free to accept or reject for himself."

The second part of the chapter takes up, as I have already indicated, the subject of evolution. It begins with a recognition and demonstration of the unusually favorable condition of the infants of Quebec as regards science.

"With us," writes the good Abbe, "the little child when it has well learned its catechism is sure of the solution of the most grave problems which can disturb the human mind; it is in possession of the truth on the most important of questions. It knows, for example, the existence of God, that is to say the existence of the eternal Being whose perfectness and power are infinite. It knows that God has created, that is to say produced by an act of His will, the whole visible and invisible universe; and

as regards our earth, it knows that God has created all the kinds, mineral, vegetable and animal that are found on it. The science of this little child is then already immense, and it is certain."

In painful contrast to this, the teacher finds that "in other lands there are unfortunately men who pass for savants, who ignore or refuse to admit and even combat these truths which rest not alone upon revealed religion, but also upon philosophy and upon the natural sciences where they are impartially questioned and legitimately understood. These men attribute all the development of the world, organic and inorganic, solely to the forces of nature, and they do this either to eliminate any necessity of intervention in this development by God or to discredit the Church which He has established." However, our author admits in a footnote¹ that not all evolutionists have such perfidious intentions, these others being engaged in following the chorus-masters of evolution simply by their lack of scientific knowledge and capacity for reflection, or because they wish to be believed to be in the scientific swim, *à la mode*.

M. Huard then proceeds to a brief setting forth of the actual hypothesis—the absurd hypothesis—of transformism, and of the trivial and thoroughly exploded alleged factors of this evolution: namely, natural selection, the influence of the use of organs, and the influence of the environment. "It is necessary to add that these famous principles of the evolutionary hypothesis have no longer many partisans to-day, because the actual facts have proved their unreality. It is well, however, to know them at least by name, because of the historic interest which still attaches to them."

M. Huard then offers a series of scientific criticisms of evolution which are sufficient in themselves to make untenable any belief in it, without making appeal at all to those other

¹ "Il ne manque pas, assurément, d'évolutionnistes qui n'ont pas ces intentions perfides, et qui ne se sont engagés à la suite des coryphées du transformisme que par défaut de science ou de réflexion, ou pour suivre ce qu'ils croient être le courant scientifique du jour."

presumably even more convincing "*motifs tres graves*" that the theologians and philosophers have for disproving the hypothesis of the evolutionists.

These objections to evolution, "drawn exclusively from the domain of science," are as follows (quoted unabridged and unmutated):

"1. The great objection that can be made, *a priori*, to evolution, and one which should make unnecessary all discussion, is that it is impossible to cite in its favor a single fact, well determined and legitimately interpreted, which shows that a single species has certainly evolved into another species. It is evident that a single fact of this kind would be sufficient, if not to establish solidly the hypothesis of evolution, at least to break much of the force and worth of the arguments of the adversaries of the hypothesis.

"2. As regards man himself, one has gone so far as to attribute to him for ancestor, the monkey, which by successive betterments should have finally become the human creature. Only, one can give no proof of this transformation; one knows none of the intermediate beings which should have formed an uninterrupted series between the monkey and man. Let us add that whether we consider the cranial development, or the anatomical structure, there are very great differences between man and even the most perfectly constituted monkey. It is the intellectual faculties, above all, which offer no ground of comparison between man and monkeys. It is necessary then to admit, from the scientific point of view, the direct creation of man by God.

"3. Just as the human being has remained the same from the beginning, so also have the animal and plant kinds remained the same, as proved by the study of fossils of all the geological epochs. There is not the least proof that a single species can, in however long a time, become another species. There have been, without doubt, both with man and with animals and plants, changes due to climate, nutrition, the soil, etc.; these changes have given rise to *varieties* more or less stable, within the species, but never to new species. The trilobites, for example, whose history can

be followed in the geological strata up to their very end, since they did not persist beyond the Tertiary epoch, have offered in only a dozen of their three or four hundred species, no more than slight variations, which were not even completely maintained by their descendants.

"Evolution, *understood in a very restricted sense*, can then show us new varieties that only culture or other causes can produce; but there its power ceases, as experiment has demonstrated.

"4. Paleontology testifies that species have not appeared, from the beginning, as a series of successive, ever better stages, but they have appeared suddenly and without relation to the species existing before. And they have appeared all at once in all their relative perfection.

"5. If evolution had, as it is claimed, produced the perfecting of species, the last come among organisms would be the most perfect. Now, the study of fossils proves that the contrary is often true. For example, the most ancient fishes, the first sea-urchins, the oldest plants, the Carboniferous amphibia, were more perfect than the fishes, sea-urchins, amphibia and plants of to-day.

"6. It is not superfluous to add to what has preceded that since the beginning of historic time there has been recorded no sign of the passing of one species into another, neither among the plants nor animals.

"The conclusions to draw from all this are: (1) that the fixity of species is a scientific truth clearly and solidly established; (2) that God himself, author of all that exists outside of himself, has directly created man and all the animal and plant species."

To add anything to this is to produce the anti-climax. Yet it must be noted that Abbe Huard's text-book has not gone wholly without criticism in French Canada. In *Le Pays*, of Montreal, a writer took some exception to the Abbe's position on evolution. *Le Pays* was reprimanded by the Archbishops of Montreal and Quebec and the reading of the journal interdicted. In *Le Naturaliste Canadien* (October, 1913) (his own paper) the Abbe Huard refers appreciatively to the incident, and mentions

that the single one of the pro-transformism arguments of the writer in *Le Pays* which remains in his memory is, that the best geologists of the United States believe in evolution. The Abbe justly remarks that the argument does not seem to him overwhelming. For, he adds, they and even most geologists of the English language and protestant faith are partisans of evolution because of their lack of philosophic and religious instruction.

V. L. K.

STANFORD UNIVERSITY, CAL.

A SIMPLE APPARATUS FOR ILLUSTRATING PHOTOSYNTHESIS

THE use of experiments, illustrating the various physiological processes in plants, are coming more and more into use in connection with the teaching of elementary botany in the secondary schools. Unfortunately the funds available for the purchase of apparatus are so limited in many of these schools that the teacher has to resort to the method of making the various experiments before the class, while the students make notes on the results, etc., to be written up in their laboratory notebooks later. Such a method as this is very good if nothing better is available, but of course the best results are obtained by the students themselves making as many of the experiments as possible. I devised the following simple apparatus for illustrating the necessity of carbon dioxide and light in photosynthesis. Since it has worked with success, I thought that a short account of it might be justified.

Ordinary bottle corks, about 2 cm. in diameter, and 1 cm. thick, should each have a hole cut through the flat side with a large cork borer. The holes should be about 1.5 cm. in diameter. Through one side of each of the cork rings thus formed, a small hole should be made for ventilating purposes. The large hole in each ring should now be covered on one side by cementing on a small piece of mica, or, if mica is not available, small round cover glasses will do, but will require more careful handling subsequently as the glass breaks more easily than the mica. A sufficient number of these discs should be made to provide

each student with six of them, two of which should be blackened to exclude the light.

In order to perform the experiment successfully a bright day should be selected, and only such plants should be used as have the stomata on the lower sides of the leaves. Plants with the stomata on both surfaces can be used, however, provided that the upper surfaces of the leaves used in the experiment are greased with cocoa butter or vaseline. The plant should be left in the dark long enough for the starch to be removed from the leaves before the experiment is started.

The cork discs, which have just been described, should be pinned to the leaves in pairs, one on the upper surface, and another on the lower surface opposite it so as to form small enclosed chambers in each instance. The blackened discs should constitute one pair so as to form a dark chamber. In order to exclude carbon dioxide the lower chamber of one of the other pairs of discs should contain small lumps of soda-lime, while the third pair will serve as a control to show that the presence of the discs themselves does not interfere with starch formation.

After the plant has stood in the sunlight for a few hours the leaves upon which the experiment is made should be removed, boiled in water, left in alcohol for a time and tested for starch in the usual way. If the experiment has been properly conducted, no starch will be present where carbon dioxide and light have been excluded, but it will be present in abundance under the discs used as a control. Groups of from two to four students can work together if the class is large and the number of discs limited.

It has been found that rather large-leaved plants with stiff petioles are better for use, in which case one leaf is sufficient for the three sets of discs. If plants with delicate leaves are used the discs can be supported by bending short lengths of soft iron wire at right angles near one end of each, and inserting the bent end in the side of one of the discs in each pair, while the other end of the wire is stuck into the soil below.

UNIVERSITY OF WISCONSIN

EXPEDITION TO THE AMAZON

TO THE EDITOR OF SCIENCE: Mr. Algot Lange, of New York, writes from the headwaters of the Cairary and Mojū in the Amazon region, Brazil, as follows:

I took my 6-man canoe above 5 long and dangerous rapids at the headwaters of the Mojū and Cairary rivers and after 15 days search I got in touch with this virgin tribe. I use the term virgin because, as I sit here alone (the only non-savage man) among about 50 Indians, I see how absolutely untouched and unspoiled this tribe is. They use stone axes and I am now showing them the use of steel axes.

Their language is not Tupi. What stock can it be, Arowak or Carib? They are agriculturists and have felled about 30 acres of jungle, with their stone axes—it looks to me as if they must have chewed the trunks. They grow cotton.

The men go nude absolutely. The women wear a narrow, colored loin-cloth.

I am received very hospitably. I am here in commission by the government [of Brazil] to look up the indigenous tribes and ascertain their different social and economic possibilities and their most urgent needs and the best way of entering into friendly relationship.

Some of the men have almost Hebraic features with brown eyes. They are tall and muscular in build. They have great skill with the bow and arrow, one bow for tapir and jaguar hunting being eight feet long.

Secretary, Explorers Club

November 5, 1913

QUOTATIONS

FREE SPEECH AND THE FACULTY

If there is one place that freedom of thought and speech should be safeguarded, it is in our college and university faculties. Presumably, no professor is obliged to wear the gag, yet it is worth observing that members of the Political Science Association have seen fit to appoint a committee "To examine and report upon the present situation in American institutions as to liberty of thought, freedom of speech and security of tenure for teachers of political science." It may be that this measure

is preventive rather than remedial. It may be that these instructors in political sciences apprehend pressure by means of the various endowment, retirement and pensioning funds and take this method of safeguard against a possible dilemma arising therefrom. But it is even more probable that the unpleasant experiences of certain of their number who have come into collision, by one means or another, with sectarian prejudices, sinister interference or powerful political rings have not been without a prompting effect. With the exception of the state universities, most of our academic institutions are, of course, dependent on the liberality of private donors. It is well known that the terms of these gifts are often embarrassing—half a million to build a museum for the testator's collection of private hobbies, when the institution needs a dormitory or a library. The difficulty is that a donor who is placing an institution as deeply under obligation as may be represented by a gift of hundreds of thousands would need to be a very extraordinary and superior person not to conceive that some sort of deference was due his opinions in return. It speaks well for the grade of men who have thus far endowed our colleges that there has been comparatively little interference with the truths they teach, at least so far as the public has been informed—what private griefs they have we know not. But as lines of political cleavage grow more distinct, as they promise to do, it will become increasingly difficult to maintain this attitude of non-interference, and it may be that this action of the professors of political sciences will yet prove to have been well-timed.

The episode raises the whole question of intellectual liberty. Each age has thought it won, and each age has seen a new difficulty arise out of the vanquishing of the old. The universities, whatever their faults, have always been sanctuaries for independent minds. Unless they are so maintained, they will hardly be worth the name. The distinction between liberty and license in the citizen is recognized and enforced. The same principle underlies all academic independence.—*Boston Transcript*.

"FREEDOM" AND FEES

It will, perhaps, do no harm to speak a little plainly of some aspects of the inquiry just instituted by the American Political Science Association into "the present situation in American educational institutions as to liberty of thought, freedom of speech, and security of tenure for teachers of political science." . . . The one point in the definition of the field of inquiry made by the association that is open to doubt and to discussion is "the security of tenure for teachers of political science." Here is where the assumptions to which we have referred come in. The gist of the matter is in the question how far a teacher of political science or of any other subject is entitled to retain his place and his pay when his teaching is not satisfactory to the trustees who are responsible for the institution in which he is employed.

That question is in some degree begged by the coupling of security of tenure with freedom of speech, as if the right to the former went with the right to the latter and as if a man not only had an inalienable right to teach whatever he chose, but a right equally inalienable to be paid for teaching it. That theory seems to us to need only to be stated to be rejected. It appears to us too clear to require discussion that the trustees of any institution of education ought not and can not surrender absolutely all control over the teaching in that institution to the men or the women who at any given moment happen to hold places in it. Nor is the matter changed materially if the trustees agree to turn over the control of the teaching to the faculty or to certain members of it. . . . Possibly the committee of the Political Science Association, with due study and reflection, in cooperation with like bodies, may be able to present some general rules or principles that may be useful. In the meantime it does no harm to suggest at the outset that there is no necessary, or even close, connection between the right to freedom of speech and the claim to be paid for speaking out of the funds of an institution the managers of which regard the speaking as mischievous.—*New York Times*.

SCIENTIFIC BOOKS

Lebensgewohnheiten und Instinkte der Insekten bis zum Erwachen der sozialen Instinkte, geschildert von O. M. REUTER. Vom Verfasser revidierte Uebersetzung nach dem schwedischen Manuscript besorgt von A. und M. Buch. R. Friedländer und Sohn, Berlin, 1913. Pp. xvi + 448; 84 text-figures.

This is the first of three volumes which Dr. O. M. Reuter planned to publish on the habits and instincts of insects. It treats only of the solitary species; the other volumes were to be devoted to the Socialia and to a general account of the sense-organs and the comparative psychology of insects. Most regrettably death has intervened to prevent the author from carrying out his plan and we are left with a single volume, which, however, is complete in itself.

The general account of insect behavior with which the work opens follows conventional lines. The activities are regarded as largely "instinctive," though the author is careful to state that some of them may properly be called "intelligent." Owing to the close association of instincts and bodily organization, he speaks of a "morphology of instincts and habits" and throughout the work views them from the evolutionary, or genetic standpoint. They are classified on a teleological basis, however, according to the problems which the insects have to solve in their daily lives. After an introductory chapter on the active and quiescent stages and the length of life of insects, the habits are arranged rather roughly under three heads, according as they subserve the purposes of nutrition, protection or reproduction.

The consideration of food-habits, though comprehensive, presents little that is new, the species being divided into omnivorous (Pantophaga), herbivorous (Phytophaga) and carnivorous (Sarcophaga). The two latter groups are each subdivided into Monophaga and Polyphaga, according as the insects derive their food from a single plant or animal or from several species. Two other groups of insects, the Necrophaga and Coprophaga, which feed on corpses and excrement, respectively, are also recognized. Parasitism is included under

the nutritive instincts, a conception which necessarily leads to a rather narrow and distorted treatment of this multifarious phenomenon. The insects that feed on other animals are divided into three groups: typical predators (Raptoria) parasitoid predators (Parasitoidea) and true parasites (Parasita). The parasitoids include such forms as the so-called "parasitic" Hymenoptera, namely, the chalcids, ichneumonids, etc., which in their larval stage feed on the eggs, larvæ or pupæ of other insects, but as adults do not depart in structure from the non-parasitic members of their order, whereas the Parasita live even as adults on the bodies of certain hosts and also in this stage exhibit modifications of structure which adapt them to their peculiar life. At first sight this classification seems to be very satisfactory, but it breaks down on closer examination. If it were adopted one would have to classify the male Strepsiptera as parasitoids and their females as parasites. Moreover, Reuter's conception of parasitism is too narrow, because it includes only food parasitism and excludes phoresy (which Reuter, for some unknown reason, writes "Foresie") and brood parasitism. Reuter is, in fact, compelled to expand and modify his conception of parasitism as soon as he comes to consider the parasitic wasps and bees.

Commensalism, and more especially mutualism, are also somewhat too narrowly restricted by their inclusion under the nutritive instincts. Various forms of the migratory instinct are likewise considered under this head, as are also the various methods adopted by insects in protecting themselves from competing consumers. This latter subject forms a transition to the protective instincts proper. It is interesting to note that Reuter treats the toilet instincts ("Reinlichkeitsinstinkte") as protectives, since they have a sanitary value, no less than the methods of protecting the organism against excessive cold, heat, moisture, etc. Protection against enemies is distinguished as passive and active, the former comprising the cryptobiotic instincts (in the sense of Willey), protective coloration, mimicry, etc., the wonderfully diverse methods of forming the larval and pupal cases,

autotomy and "death-feigning," while the actively protective behavior includes the use of the repugnatorial glands, the peculiar phenomena of "autohemorrhæa," or emission of poisonous blood (often charged with cantharidin) from the joints of the legs in various larval and adult beetles, and phosphorescence, although this is in some cases passive (larval fire-flies) or connected with courtship (adult fire-flies). Reuter's treatment of the much-discussed subjects of protective resemblance and mimicry is very conservative. Any consideration of the many doubts which have been cast on these subjects by recent authors, especially in continental Europe, is omitted, as we should expect from the author's assumption that protective colors and devices are essentially passive, instead of being the stable results of once active adaptations.

Reuter devotes to what he calls the "instincts of metamorphosis" a chapter including the peculiar larval activities which leave the pupa in situations best adapted to the eclosion of the adult insect. This chapter clearly shows how impossible it is to draw a hard and fast line between the general physiological and morphological processes, on the one hand, and the instinct activities, on the other.

The reproductive instincts include the phenomena of courtship, that is, the exhibition by one sex of its peculiar movements, colors and structures, photogenesis, the use of the osmateria, or scent-glands, and such extraordinary pieces of behavior as that of the ballooning male Empidid flies described by Girschner, Mik, Aldrich, Hamm and others, and finally oviposition and the extension of maternal and in rare cases also of paternal care to the eggs and larvæ.

The discussion of these and the foregoing subjects occupies about two thirds of the volume; the remainder is devoted to an excellent summary of the habits of the solitary wasps and solitary bees, and closes with two chapters on the adumbrations of social life noticeable in some non-social insects. The peculiar mixed arrangement of the materials relating to the wasps and bees is evidently intended to call attention to the parallelism or convergence in the phylogeny of their habits,

but it might have been better to have completed the account of each of these groups by itself and to have added a short chapter on the similarities due to convergence.

This very summary description of the contents of Reuter's work unfortunately fails to give any adequate conception of the large amount of very interesting and valuable reading it contains. As the first work to give a comprehensive survey of the habits of the solitary insects it is eminently successful. The writer has collated the essential facts from a very wide perusal of both the older and most recent literature on insect ethology, and has presented the matter in a very succinct and attractive style.

The volume ends with a well-selected bibliography of 60 pages and a good index. The bibliography includes many recent works on the social insects not cited in the text. There are few erroneous statements of fact like the one on p. 365, where it is said that ants appeared "in grossen Massen" in the Jurassic, immediately following the correct statement that "the existence of social Hymenoptera can not be demonstrated till Tertiary times." In the same paragraph we find the erroneous statement that termites occur in the Carboniferous.

The cuts in the text are mostly old, unattractive and poorly printed. Some of them set one to wondering why there are no good figures of many of our common insects, and why our author should be compelled to use, *e. g.*, the time-worn figure on p. 32 of the *Cicindela* larva, which is so small compared with its burrow that it could not possibly use its legs and dorsal horn in the manner described in the text. The number of typographical errors is considerable and many of them have not been corrected in the two pages of errata at the end of the volume. If it be true, however, as the reviewer is informed, that Reuter was blind for several years before his death, all of these errors and the poor selection of figures may be readily explained and pardoned.

W. M. WHEELER

Mind and Health, with an Examination of some Systems of Divine Healing. By ED-

WARD E. WEAVER, with an Introduction by G. STANLEY HALL. New York, The Macmillan Company. 1913. Pp. xv + 500. Price, \$2.00 net.

The occasion for this book is the recent interest of some of the clergy in the practise of psychotherapy. After some account of the history, scientific basis and technique of psychotherapy, and a critical discussion of the merits of Christian Science, divine healing, "new thought," the Emmanuel movement, etc., the author reaches the conclusion that the church and its ministers can rightly and beneficially take a share in treating the sick. Religious faith and fervor, he urges, are a source of vitalizing energy which can be drawn upon for the maintenance and restoration of health. Character and health go together, and the minister of religion is, therefore, charged, to a degree, with the care of health. He should be acquainted with the scientific aspects of psychotherapy and should work in harmony with the physician.

R. S. WOODWORTH

Labrador. By WILFRID T. GRENFELL and others. New edition. New York, The Macmillan Co. 1913. \$2.50 net.

The first edition of this standard work was recognized as a valuable addition to the literature on this practically unknown part of North America. The chapters on history, geology, Indians, birds, insects, mammals, etc., are admirable contributions from recognized experts.

While the new chapters by Dr. Grenfell have no scientific value, yet they are of popular interest, treating of animal life and of conservation. He sets forth pleasantly the lack of daring courage on the part of the bear and wolf, the domestication of the caribou, the food-value of the porcupine, the destructiveness of the lynx and the wiliness of the wolverine. On animal life he tells of the long winter experiences, when the bears sleep, the rabbits eat young birch, and the porcupine keeps to conifers. He adds: "Strangely enough none of the mammals rely on sight for protection. The difficulty of survival is in-

creased by constant warfare. The squirrel is never safe from the lynx, the caribou from the wolf, the rabbit from the fox."

As to conservation both sea and land game are steadily diminishing. The forests are fire-devastated, and immense waste continues in many directions. Indians and Eskimos are decreasing, and yearly bands escape starvation only through charity. Dr. Grenfell recognizes that the aboriginal inhabitants and the lower order of animals must go to the wall. He is however optimistic as to the development of Labrador; with the exploitation of the pulp forest for the whites, and by the reindeer herds for the natives.

The index completely ignores the new matter, an unfortunate oversight of the publishers.

A. W. GREELY

BOTANICAL NOTES

THE FOURTH INTERNATIONAL BOTANICAL CONGRESS

ATTENTION of botanists is called to the "first circular" in regard to the next International Botanical Congress, recently issued by the Organizing Committee.

Dear Sir and Colleague,

The International Botanical Congress, held at Brussels in May, 1910, decided, on the invitation of the Royal Society of London, that the next meeting of the congress, in 1915, should be held in London.

At a representative meeting of British botanists, held in London on May 10, 1911, a provisional bureau was nominated, consisting of three presidents (Professor F. O. Bower, Sir David Prain and Professor A. C. Seward) and a general secretary (Dr. A. B. Rendle). The bureau was empowered to cooperate with the permanent bureau of the Brussels Congress and to arrange for the appointment, in consultation with the British botanists, of an organizing committee. This organizing committee was elected at a general meeting of British botanists held in London on March 11, 1912; and at a second meeting held on May 17, an executive committee was appointed. A number of distinguished patrons of botany were also invited to lend their support to the congress.

The following general regulations for the conduct of the congress have been approved by the executive committee:

1. The Fourth International Botanical Congress shall be held in London from Saturday, May 22, to Saturday, May 29.

2. Membership of the congress shall be conditional upon subscribing to its regulations and the payment of a subscription of fifteen shillings. Members will receive all the publications of the congress. Ladies accompanying members may attend the meetings and excursions of the congress on payment of ten shillings each.

3. The work of the congress shall include the different branches of botanical science; and the congress will also carry on the work on (1) nomenclature, and (2) bibliography and documentation, left over from the previous meeting.

The permanent bureaux entrusted with the work concerned with (1) nomenclature, and (2) bibliography and documentation will act in conjunction with the executive committee.

4. Any language may be used in the discussions; if desired by the members, propositions shall be translated forthwith into English, French and German. English shall be the official language of the congress.

Particulars of meetings, discussions, excursions, etc., will be issued later.

American botanists are reminded that it is not too early to begin making arrangements for this congress. Communications may be addressed to the general secretary, Dr. A. B. Rendle, keeper of the department of botany, British Museum, Cromwell Road, London, England.

A NEW KIND OF BOTANICAL TEXT-BOOK

It is not often that the reviewer of books finds one of a new type, and especially is this true in regard to elementary text-books in science; yet in John G. Coulter's "Plant Life and Plant Uses" (Am. Book Co.) we find just such a case. It is so unlike the usual book designed for beginners in botany that the author allows the use of the word text-book only with particular limitations and restrictions. Avowedly intended as "a foundation for the study of agriculture" and "domestic science" the author has not al-

lowed this purpose to change materially the presentation of "the large essentials of plant life." "The effort is to include what has proper place in the education of *all* young people," and he distinctly excludes those special matters which are best relegated to agriculture, horticulture, domestic science, forestry, etc. In other words, we have here what the author believes all young people should know about plants as a general foundation for the subjects named, or even as a preparation for college botany. The present reviewer is in hearty accord with this educational theory, and he believes that in all well-considered schemes of education pure science must precede applied science.

The book is written in an easy, almost conversational style, and one wonders just how it is likely to be used by the ordinary teacher. It can scarcely be "recited" by the pupil, and possibly this may be a point in its favor. Perhaps this is why the author has added questions after the chapters, usually a feature of doubtful value, from the temptation it offers to the illy-prepared teacher to hold the book and ask the questions noted down before him.

Looking through the book, one is struck by a freshness of statement, showing that the author feels that he has a message for the high-school pupils of the country, and this continues with unabated enthusiasm from the first paragraph of the introduction to the closing paragraph of the book. It should do much to place high-school botany in this country upon a higher plane than it has ordinarily attained.

A NICE LITTLE DIATOM BOOK

One of the most attractive little books that we have seen in many a day is one entitled "Bacillariales" by H. v. Schönfeldt, and published by Gustav Fischer, of Jena. It is volume 10 of the series of booklets now in course of publication entitled "Die Süßwasserflora Deutschlands, Österreichs und der Schweiz" and edited by Professor Doctor Pascher, of Prag. There are to be sixteen of these booklets, bound in limp cloth, each meas-

uring about 11×19 cm. The book before us gives ten pages to structure, cell-contents, movements, reproduction, collecting, mounting and the literature of the group. Then follow 163 pages of systematic descriptions, the general treatment following that by Schütt in Engler and Prantl's "Natürlichen Pflanzenfamilien." Fourteen pages are given to the round diatoms (Centricæ), including eight genera and thirty-five species, while about 150 pages are given to the long diatoms (Pennatæ) in which are included about 40 genera and 390 species. These figures emphasize the statement often made that the round diatoms are mostly marine, and the long diatoms mostly inhabitants of fresh waters. Probably the truth is that in fresh waters we find many more long diatoms, because there are many more of them in the world at large, but this does not wholly account for the great disparity in numbers.

There are 379 cuts in the text, which must help the student greatly in his attempts to understand the structure and especially the markings of the cell-walls. A well-arranged index of scientific names closes this handy little book. One can not lay down this book without the wish that some day we may have something like it for this country.

THE UNIVERSITY OF NEBRASKA

SPECIAL ARTICLES

SUSCEPTIBILITY GRADIENTS IN ANIMALS

THE writer has called attention in several papers¹ to the existence of axial gradients in rate of metabolism in planarians and other forms and their significance in relation to polarity. During the past summer in the course of other work at Woods Hole the opportunity presented itself to examine various forms belonging to different groups and various embryonic and larval stages for the existence of such gradients.

The method used was that of determining the relative susceptibility of different regions

¹ *Jour. Exp. Zool.*, XII, 1912; *Arch. f. Entwicklungsmech.*, XXXV, 1913; XXXVII, 1913.

of the body to certain narcotics and poisons, KCN, alcohol and ether being chiefly used. To concentrations of these and various other substances which kill within a few hours without permitting any acclimatization the susceptibility varies in general with the rate of metabolism, or of certain fundamental metabolic processes, *i. e.*, the higher the rate of these processes the greater the susceptibility and the earlier death or cessation of movement occurs.² Death in these reagents is usually followed very soon, often almost at once, by rounding, separation or disintegration of the cells, so that the time of death can be approximately determined by visible changes of this kind. Results obtained in this manner can be controlled by removing the animals from the solution at different periods and determining when recovery ceases to occur and experience has shown that these two methods of procedure give essentially similar results. In this way the following forms were examined.

In *Nereis virens* the regional susceptibility of developmental stages from the beginning of cleavage to the late trochophore was determined. In the early cleavage stages the micromeres are more susceptible to KCN 0.005 *m.* than the macromeres. They not only disintegrate before the macromeres when the eggs remain in the solution, but if the eggs are returned to sea water at the proper time the micromeres alone are killed and the macromeres recover and resume division, giving rise to defective larvae.

At the stage when gastrulation is nearly completed the somatic plate region is apparently the most susceptible region of the embryo, and by return to water at the proper time it is possible to obtain larvae which do not elongate posteriorly and do not form the three larval segments. If the embryos at this stage are left for a longer time in KCN before return to water, both somatic plate and some or all of the macromeres are killed and the intact portion consists of more or less of the ventral portion of pre-trochal and post-trochal ectoderm with or

without a part of the macromeres. Evidently the most susceptible regions at this stage are first the somatic plate, and second, the dorsal part of the pre-trochal region and the macromeres.

In the developing egg of another annelid, *Chaetopterus pergamentaceus*, the relative susceptibilities of different regions are much the same. In the early stages the animal pole shows the highest susceptibility and in later stages a second region of high susceptibility appears in the somatic plate. In still another polychæte, *Arenicola cristata*, the apical region and somatic plate of the young trochophores are the most susceptible regions. The early cleavage stages of this species were not obtained.

In *Nereis* and *Chaetopterus* the region about the animal pole is clearly the region of greatest susceptibility, *i. e.*, of greatest metabolic activity in the early stages of development. Later the activity in this region becomes relatively less in *Nereis* as differentiation of the apical larval region advances and the somatic plate becomes the most active region of the egg. But in *Chaetopterus* the apical region retains its susceptibility to some extent at the completion of gastrulation, and this region and the somatic plate appear as distinct regions of high susceptibility. In other words, at the beginning of development an axial metabolic gradient exists with the region of highest rate about the animal pole, but as development proceeds this gradient is altered from its primary simple form by the increase in activity of the cells which give rise to body segments and later by decrease in activity in the animal pole region.

In the egg of the sea urchin *Arbacia* in KCN 0.005 *m.* a distinct susceptibility gradient was observed during cleavage, death and disintegration beginning at one region of the egg and proceeding along an axis, but it was not possible to determine whether the region of highest susceptibility was always the animal pole, though in many cases it certainly was. In the later gastrula and pre-luteus stages this simple gradient was complicated by the appearance of high susceptibility in the re-

² Child, *Jour. Exp. Zool.*, XIV., 1913.

gions where the arms were beginning to develop.

Since in *Nereis*, *Chætopterus* and *Arbacia* the different susceptibilities of different regions of the developmental stages make it possible to kill with more or less exactness certain parts of the embryo while other parts may recover and continue development, this method may prove of some value in further investigation of the regulatory capacities of the less active regions when isolated from the influence of the more active.

The adult forms of a number of species from various groups were examined for a susceptibility gradient. In the hydroid *Pennaria tiarella* with KCN 0.0025 *m.* and 0.005 *m.* such a gradient appears very clearly in the body of the hydranth, death and disintegration beginning at the distal end of the manubrium and proceeding proximally. A similar gradient exists in the medusa buds of this species. Besides this it was observed that the full-grown hydranths at or near the tips of stem or branches were in general more susceptible than the more proximal. This difference may be due to external factors such as the lower oxygen or higher CO₂ content of the water about the more proximal hydranths in consequence of the greater number of hydranths in a given area, but it seems more probable, in the light of various data concerning the polarity of plants, that this difference in susceptibility of distal and proximal hydranths is the expression of an axial gradient in the colony.

In several other species of hydroids examined at Woods Hole and at La Jolla, California, among them *Tubularia crocea* and *Corymorpha palma* the gradient in the hydranth body is similar to that in *Pennaria*.

The ctenophore *Mnemiopsis leidyi* shows a distinct gradient in susceptibility along each row of swimming plates. The susceptibility of these animals to KCN is very high and most experiments were made with KCN 0.0000375 *m.*—0.0005 *m.* Rhythmic movement of the plates ceases first at the central end of each row, *i. e.*, the end nearest the apical sense organ, and last at the peripheral end. Before

movement has entirely stopped in the apical region the rhythm of the plates in the peripheral half or third of the row becomes different from the central rhythm, being usually more rapid and in some cases irregular or periodic. In two cases a perfectly distinct reversal in direction of the impulse was observed at the peripheral end of a row after movement at the central end had ceased. In this case the impulse started at the extreme peripheral end of the row and traveled some distance in the central direction, finally dying out. This continued for an hour or more before movement at the peripheral end ceased.

This susceptibility gradient is undoubtedly a gradient in the nerve and not in the plates themselves, for the plates do not die in KCN until long after rhythmic movement ceases, and as long as they remain alive direct contact stimulation of single plates produces slight movements of the plate stimulated. However, a slight susceptibility gradient does exist in the plates themselves as is evident from the fact that the plates at the central end of the nerve die first and death proceeds peripherally. The time of death is readily determined, for when they die the plates lose their interference colors and become white and opaque.

As regards the general ectoderm of *Mnemiopsis*, it is difficult to determine the time of death accurately, but observations thus far indicate that the disintegration of the ectoderm proceeds from the apical region.

During the course of my observations on susceptibility gradients Dr. Tashiro called my attention to his discovery of a quantitative gradient in CO₂ production in the claw nerve of the large spider crab, *Libinia canaliculata*: this is a long nerve which readily separates into small strands and is therefore favorable for observation of any structural changes which might occur in connection with death in solutions of narcotics. The nerve is mixed but is believed to consist largely of efferent fibers.

Since there is some evidence in the work of various authors that a gradient of some sort exists in the nerve, the attempt was made to

determine whether a gradient would appear in the structural death changes. A number of nerves were observed in various concentrations of KCN from 0.001 *m.* to 0.01 *m.* In these solutions the fibrillæ become after a time irregular in outline and more or less varicose so that the strand appears more or less granular instead of fibrillar like the fresh living nerve. The preparations showed some indications of the progression of the change from the central to the peripheral end of the nerve, but the changes were so slight that the possibility of a subjective factor being concerned could not be neglected. In the attempt to obtain more distinct structural death changes other narcotics were used, and it was found that in ethyl ether the fibrillation almost completely disappeared and the strands became very distinctly granular in appearance in consequence of irregular swelling and varicosity of the fibrils. In 1 per cent. ether or somewhat lower concentrations these changes occur, slowly requiring several hours for completion, and a very distinct gradient in their occurrence is visible. The change from fibrillar to granular appearance begins at the two ends of the nerve very soon after it is brought into the solution, and a distinct gradient in this change can be seen extending a few millimeters peripherally from the central end and a shorter distance centrally from the peripheral end. This first change remains limited to the two terminal regions of the nerve and is undoubtedly associated with the stimulation and injury resulting from severing the nerve at these two points.

Later, however, the change begins to progress along the nerve from the central toward the peripheral end, but the change at the peripheral end progresses only very slowly or not at all in the central direction. From this time on a distinct gradient in the change is visible until it has progressed along the whole length of the nerve. Except in the terminal region adjoining the peripheral cut end the death change always progresses in the peripheral direction. The peripheral third of the length may be entirely unchanged at a time when the central third or more has com-

pletely lost its fibrillar appearance. When long strands are so arranged that central and peripheral regions are side by side in the same field of the microscope the differences between the two regions are very striking. If the nerve is crushed or injured at any point short gradients appear on both sides of the injury, but do not extend to any great distance before the general change reaches this region in its progress peripherally.

The existence of this centro-peripheral gradient in the death changes of the nerve fiber in narcotics must mean that a gradient of some sort exists in the living nerve and if the action of the narcotics is of the same character here as in other cases we must conclude that this gradient is associated with metabolism and that the rate of metabolism or of certain metabolic processes is in general higher at the central end and decreases peripherally in this nerve.

That metabolic gradients occur very widely it not universally, at least during the earlier stages of development in axiate organisms and in structures, is evident from the data of embryology. The so-called law of antero-posterior development must be the expression of an axial metabolic gradient. And as regards plants there is a large body of evidence which indicates that the vegetative tip possesses a higher rate of metabolism than other regions of the same axis. Even in the unicellular body of the ciliate infusoria and in various other cells which show a morphological polarity the writer has observed a susceptibility gradient. In view of the facts it is impossible to doubt that such gradients are in some way closely associated with polarity in organisms, and various lines of experimental evidence which can not be considered here indicate that they constitute the dynamic basis of polarity. There are, moreover, many facts which suggest that the establishment of a gradient of this kind is the first step in individuation in axiate organisms.

**Polygon Cameras**

"THE CAMERA OF QUALITY"

with

Rietzschel Double Anastigmats

are the embodiment of all that is desirable in cameras. They are compact, small, and light in weight, yet they are very reasonable in price; "They fit the Pocket." They are made from miniature size up to 5 x 7 inches, in all styles. All are built of light but indestructible metal; all are leather covered; all have leather bellows; all have rising, falling and cross front; all have detachable lensboard; all have quickly reversible ground glass; all are fitted with double anastigmats, the better ones with the finest cemented lenses ever put on the market, in compound shutter.

We also sell

STANDARD LABORATORY MANUALS

Methods in Plant Histology. With Illustrations. By CHARLES JOSEPH CHAMBERLAIN, Associate Professor of Botany in the University of Chicago. 272 pages, 8vo, cloth, postpaid, \$2.39.

Education. It is an excellent book for the individual worker and for classes in colleges.

Animal Micrology. By MICHAEL F. GUYER, Professor of Zoology in the University of Cincinnati. 250 pages, 8vo, cloth, postpaid, \$1.88.

Science. A concise, eminently practical, and well-classified treatment.

A Laboratory Guide in Bacteriology. By PAUL G. HEINEMANN, Instructor in Bacteriology in the University of Chicago. 216 pages, 12mo, cloth, postpaid, \$1.59.

American Journal of Medical Science. A book such as this must facilitate very greatly the practical class work, for which it is most excellently adapted.

Neurological Technique. By IRVING HARDESTY, Professor of Anatomy in Tulane University. 196 pages, 8vo, cloth; postpaid \$1.87.

British Medical Journal. The instructions are thoroughly practical.

Laboratory Outlines for the Study of the Embryology of the Chick and Pig. By FRANK R. LILLIE, Professor of Embryology in the University of Chicago. 48 pages, paper; postpaid, 27 cents.

A valuable contribution toward the establishment of a standard of embryological work for students generally, and for others desiring a convenient guide to the order of study of this subject.

THE CHARACTERIZATION AND CLASSIFICATION OF BACTERIAL TYPES¹

THE vast majority of students of microbial life are preoccupied with immediately practical problems, and most of them have been trained for their work from the standpoint of some practical art, medicine, veterinary science, sanitary engineering or agriculture, rather than from the more general and fundamental standpoint of the biologist. The Society of American Bacteriologists was founded as a protest against such necessary but dangerous specialization, to bring together workers in all fields for a consideration of their problems in the light of the underlying, unifying principles of bacteriology as a member of the group of the biologic sciences. It is this ideal which distinguishes our society from any other organization in America which deals with microbial life and its effects.

It is of course fruitless to attempt to draw any sharp distinction between pure and applied science, and it would be a great pity if, as we gather year by year, we should fail to discuss together many of the more special problems of technique with which we are concerned. In particular it is well that we should exercise the widest hospitality toward those branches of our science, such as dairy bacteriology and soil bacteriology which have no technical societies at their disposal, such as are available for the specialists in medical and sanitary lines. We should be untrue to our highest mission, however, if we failed at the same time to emphasize those phases of our work in which this society of all others

¹ Presidential address, Society of American Bacteriologists, Montreal, Canada, January 1, 1914.

is peculiarly qualified to be of service, in striking sparks by the contact of experience in the different fields of bacteriology, and in viewing all our special problems by the clear light of fundamental biological principles.

The task of the biologist is the study of the reactions of the group of allied substances we call protoplasts, under the influence of various physical and chemical conditions of the environment. Instead of the pure compounds of the chemist we must deal with organisms, interacting mixtures of substances, different for each kind and even for each individual plant and animal. In very refined work such as is involved in the determination of reaction times by the psychologist or in our own studies of the action of disinfectants, even the personal equation of the individual or the individual strain must be taken into account. For most purposes, however, the species or kind of organism displays reasonably uniform characteristics, and may be used as our practical unit of study. A clear distinction between the kinds of organisms involved and a clear conception of the relation between these kinds is certainly however imperative, and a sound basis for the characterization and classification of the organisms with which we deal is one of the most pressing needs of bacteriology.

The fact that we have lacked in the past any sound system of sorting out and arranging bacterial types requires no elaborate demonstration. The question of what constitutes a colon bacillus has agitated sanitary bacteriologists for three decades and is still unsolved. And to take a still more striking and still more important case, consider the controversy as to the *Vielheit* or the *Einheit* of the streptococci, which has raged so long. Here is a group of organisms, the part played by which in a wide range of diverse diseases is found to be more fundamental—a group which I am

inclined to think produces in the aggregate more suffering and death—than any other group, except the acid-fast bacilli. Yet we are almost wholly at sea in regard to their identification and mutual relationships.

There are two very distinct types of variations characteristic of organisms in general, fluctuations and mutations, and both are well recognized among bacteria. Fluctuations are the minor quantitative differences which group themselves on a curve of frequency when a large series of individuals is studied, as a rule due to the chance effects of environment and not inheritable. Thus, for example, Walker and I (Winslow and Walker, 1909) found that one hundred different subcultures of a single strain of the paratyphoid bacillus race *A* gave acidities in dextrose broth varying between 1.1 and 1.6 per cent. normal, while a similar series of lines of race *B* gave acidities varying between 1.3 and 1.9 per cent. normal. We took the subcultures of each type giving maximum and minimum acidities and isolated one hundred secondary subcultures of each. The curves from these extreme cultures however in spite of the diversity exhibited by their immediate parent stock, went back to the curves characteristic of their respective races, with a mean value of 1.4 for race *A* and of 1.6 for race *B* (Fig. 1). These fluctuating variations are clearly of no systematic significance and must be eliminated from consideration by a study of numerous strains of the same type.

It seems on the whole most convenient to limit the term fluctuations to such non-inheritable variations as those just described. At times, however, we find in our cultures variations of apparently similar nature, but distinguished by the fact that selection among them does produce permanently different races. Thus, Goodman (1908) carried out experiments with the acid production of *B. diphtheriae* somewhat

like those with the paratyphoid strains which have just been discussed, but leading to the ultimate separation of two strains of widely different fermentative power. Rettger and Sherrick (1911) report similar results in regard to the pig-

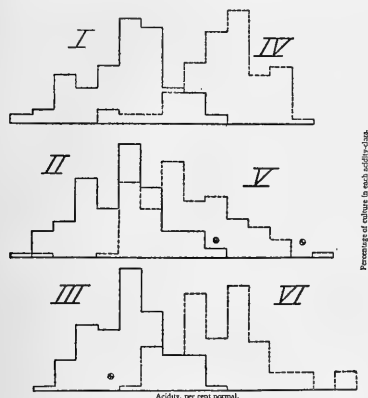

FIG. 1. ACID PRODUCTION BY PARATYPHOID BACILLI. (I.) Distribution of 100 original cultures, Type A. (II.) Distribution of 100 subcultures of descendants of maximum strain, Type A. (III.) Distribution of 100 subcultures of descendants of minimum strain, Type A. (IV.) Distribution of 100 original cultures, Type B. (V.) Distribution of 100 subcultures of descendants of maximum strain, Type B. (VI.) Distribution of 100 subcultures of descendants of minimum strain, Type B.

ment-producing power of some of the red chromogens and the resistance to mercuric chlorid of the *Aurococcus*; and in their paper the similar results of earlier observers are discussed. Such variations as these strongly suggest the pure lines of Johannsen and may perhaps for convenience be designated as pure line variations.

A distinct type of variation is the mutation, a definite sharp variation separated by a wide gap from the normal character of the type, arising spontaneously in

a certain regular proportion of the individuals of a race. Barber (1907) has shown for example that peculiar filamentous chains of cells occur, rarely, but with considerable regularity, in cultures of *B. coli*, and that by isolating these filaments and breeding from them he could get a new race, constantly showing the filamentous arrangement and possessing definite cultural characters and a fermentative power considerably higher than the normal. Similar, though less conclusive results were obtained with *B. typhi*, and in one case an apparently non-spore-forming race was derived from *B. megatherium*. A particularly interesting case is that of the fermenting mutants of the typhoid group first observed by Neisser and Massini and recently thoroughly worked out by Penfold (1912). With a number of different strains of typhoid and paratyphoid bacilli and a number of different sugar media it has been shown that an organism which does not ferment the carbohydrate in question may produce on media containing it colonies which after several days bear curious raised papillae. Subcultures from these papillae yield a pure culture of a strain which resembles the parent stock in every respect, except that it actively ferments the specific carbohydrate and forms no papillae; and this mutant breeds true. On the other hand subcultures from other parts of the parent colony produce strains which, like the original stock, do not ferment en masse, but do possess the property of throwing off fermenting mutants. Clark (1913) has recently shown that some at least of these modifications may have been quantitative only rather than qualitative, but the sharpness of the difference involved seems to warrant their recognition as true mutations.

Either fluctuations or mutations may originate as a result of protoplasmic in-

equalities in cell division and without any corresponding variations in environmental condition. Or, on the other hand, they may be causally related to changes in the chemical and physical surroundings of the organism as were those which MacDougal produced among the higher plants by injecting chemicals into the ovary and such as Tower caused by exposing potato beetles to special conditions of temperature and humidity. Changes of this sort are very familiar among the bacteria, as for example in the case of the increase in virulence on passage through susceptible animals, or the converse process of attenuation, as practised in the preparation of vaccines for anthrax and other diseases. Wolf (1909) reports a considerable number of temporary modifications and some permanently inheritable ones stimulated by exposing bacteria to the action of chemicals. White and dark red strains were thus produced from a normal *B. prodigiosus*, the resulting modifications breeding in each case true to their new type. Variations of this sort called forth by the direct effect of the environment I have been accustomed to distinguish by the term "impressed variations."

The net result of the various sorts of variability to which the bacteria are subject is to produce a condition, not different in kind, but more extreme in degree, than that which exists among more complex forms. As Bateson (1913) says: "The problem of species in its main features is presented by these organisms in a form identical with that which we know so well among the higher animals and plants." Several peculiar conditions tend, however, to make specific distinctions even more unstable among the bacteria than elsewhere. In the first place the action of the environment upon unicellular organisms is peculiarly direct and the fact that all cells are potentially reproductive removes any bar

against the inheritance of acquired characters. Again the absence of sexual reproduction must operate to preserve variations which arise from within or without. Among sexual organisms it is true that amphimixis is held to be in itself an important source of germinal variations. Yet this is true only within certain rather definite limits and beyond those limits sexual reproduction ceases or becomes infertile and thus the more divergent variations are eliminated. With fission as the normal method of reproduction, on the other hand, every variation which can arise may be handed on, unchanged. Finally the rapidity with which the bacteria multiply furnishes exceptional opportunities for the operation of selection or any other modifying force. The immense number of generations which may succeed each other in a short space of time might be expected to make boundary lines as shifting as they would become among the higher plants if a dozen geological epochs were considered all at once.

There are sharp limits to the variability of even the bacteria however and for practical purposes we find the larger groups quite constant in their general properties. As a rule typhoid germs descend from typhoid germs and tubercle bacilli from tubercle bacilli. The same yellow coccus falls on gelatin plates exposed to the air, all over the world. The same spore-forming aerobes occur in every soil, the same colon bacilli crowd the intestines of animals and men in every clime. In part at least I am inclined to believe that this is due to the direct or selective effect of similar environmental conditions producing what Jordan and Kellogg call among higher organisms "Ontogenetic species held for a number of generations true to a type simply because the environment, the extrinsic factors in the development of all the individuals in these successive generations, are

the same." The comparative fixity of the more strictly pathogenic bacteria is a striking illustration of this tendency.

In many instances we find that individual strains of bacteria exhibit an extraordinary uniformity in minor characteristics even when (or perhaps particularly when) cultivated for long periods on artificial media in the laboratory. The two paratyphoid strains, *A* and *B*, described above offer a striking instance of this. The mean acid production of the two strains was respectively 1.4 and 1.6 per cent. normal, differing only by .2 per cent. normal and the fluctuating variations, extending over a range of over 1.0 per cent. in each case, far exceed the mean difference between the strains. Yet subcultures show each strain, as a strain, breeding true to its characteristic. We find slight differences in resistance to unfavorable physical condition or to the action of some chemical disinfectant transmitted unchanged in a particular strain for generation after generation.

As a matter of fact indeed it is not alterations in the characters of bacteria while we are studying them which generally trouble us, but the fact that as we isolate these organisms in nature we find that antecedent variations have produced a bewildering confusion of slightly differing varieties or races or strains. Between well-marked types like *B. coli* and *B. alcaligenes* is a series of forms, each one differing but slightly from its neighbor, but together almost completely bridging the gap between the two extremes. The more refined our methods of bio-chemical examination, the more the types are multiplied, and the more hopeless is the confusion. When Gordon (1905) applied his nine tests to 300 different strains of streptococci, he found 48 different combinations of reactions, and MacConkey (1909) records 36 different varieties of colon bacilli characterized by

particular combinations of his seven tests. To call each distinguishable strain having definite bio-chemical properties a species and to give it a name of its own, is quite out of the question. To ignore all minor differences and maintain as specific such complex groups as are included under the term *B. coli* or *Str. pyogenes* is misleading and an effective bar to future progress.

The first principle, which has proved of prime assistance in the characterization of bacterial types, and which offers a rational compromise between either false unity or bewildering multiplicity, is the recognition of the fact that types which occur commonly among bacteria as they are found in nature are of greater systematic importance than those which occur rarely and occasionally. Of course from one standpoint every inheritable protoplasmic variant which exists is of equal importance with every other. For practical purposes, however, we must recognize certain types as "species" or "varieties" even though they may sometimes intergrade. Among the higher plants and animals such systematic units are usually recognized on the basis of discontinuity in some definite character. The more refined methods of biometry have however revealed another grade of kinds (I use this word to avoid the artificial implications of "species" or "variety"), marked by relative rather than absolute discontinuity. Frequently the measurement of some particular differential character and the plotting of a "frequency polygon," with grades of the chosen character as abscissæ and the proportion of individuals showing each grade as ordinates, shows a curve with two distinct peaks, a bimodal curve. The studies reported by Bateson on the length of the cephalic horns of the rhinoceros beetle and on the forceps length of the earwig and De Vries's observations on the petals of a chrysanthemum, are excellent examples.

In each case the peaks on the curve indicate distinct centers of variation around which the intermediate fluctuations are grouped and these constitute biologic facts of real importance, even though the types overlap and appear to blend in the valleys between the modes.

Johannsen in his recent book (1913) has discussed such bimodal curves with admirable clearness and points out that obvious phenotypes (externally recognizable kinds) may or may not represent true genotypes (characterized by germinal differences),—

Fig. 2.

breeding experiments being the only final criterion. In our bacteriological work we are making breeding experiments all the time and even though our study of mass reactions may be crude, it is free from the grosser errors due to environmental variations, and our bimodal curves indicate real protoplasmic diversity. For example, in a study of the gelatine liquefying power of the orange cocci, it appeared that the depth of liquefaction after 30 days varied from 0 to over 3.5 cm., each intermediate .5 c.c.

value being represented. Yet the frequency with which various grades of liquefaction occurred showed that only two distinct types were common (Fig. 2), one failing entirely to liquefy, including 30 per cent. of the strains studied, and the other liquefying rapidly, to the extent of 2.0-3.5 cm., including 45 per cent. of the strains. Ordinarily such a difference in proteolytic power as that between a liquefaction of 1.0 cm. and one of 3.0 would be considered important as marking a distinction between a very slowly and a rapidly liquefying type. Yet in view of the frequency curve it is both practically convenient and biologically sound to say that we are dealing with two and only two distinct types, so far as this character is concerned, one not liquefying at all and the other liquefying vigorously to an extent of 2.0-3.5 cm. in 30 days, while slowly liquefying strains may be considered as aberrant varieties.

Another example of this conception of frequency types may be taken from recent studies of the fermentative power of the colon bacilli and the streptococci. Both these groups have been split up according to their acid-producing power in a wide variety of carbohydrate media and any one sugar has been considered just as important as any other, giving almost as many types as there are permutations and combinations of the test substances used. Howe (1912) has shown for the colon bacilli, and the same thing is true for the streptococci (Winslow, 1912), that the various carbohydrate media are not fermented at random, but stand to each other in a definite "order of availability" forming what Howe calls a "metabolic gradient," such that if any member of the series is fermented the chances are that those ahead of it will be fermented also. Thus in the colon group dextrose is most often attacked, then lactose, then saccharose and then raffinose. Certain steps in the gradient are qualita-

tively far more important than others. Of 540 dextrose fermenting bacilli freshly isolated from the intestine Howe found that practically all attacked lactose. Saccharose divided the group into two approximately equal subgroups, 58 per cent. attacking this sugar and 41 per cent. failing to do so. Of the 58 per cent. all but 5 per cent. also attacked raffinose so that the dextrose-lactose-saccharose forms may be considered intermediate variants between the two main di-

FIG. 3.

visions which ferment either dextrose and lactose alone or all four sugars (Fig. 3). It seems clear that such quantitative studies furnish the surest basis for deciding which sugars are primarily important in classification and we may safely conclude that so far as these four sugars are concerned there are only two important divisions of the colon group. The use of dulcete which occupies an equally prominent place in the classification of MacConkey (1909) and Jackson (1911), rests on no such biometrical basis and we have no

good reason to think it deserves special importance. In the same way the admirable study by Stowell, Hilliard and Schlesinger (1915) of the streptococci shows that the five groups fermenting respectively dextrose only, dextrose and lactose, dextrose, lactose and saccharose, dextrose, lactose, saccharose, and raffinose and dextrose, lactose, saccharose, raffinose and salicin are quantitatively of special importance and include between them 68 per cent. of 240 strains studied.

A second conception, of much assistance in the classification of bacteria, is the principle that special weight should be given to characters quantitative or qualitative, which are found to be correlated with each other in a number of different types. The principle of numerical frequency offers a basis for characterizing the individual types and the principle of correlation a basis for classifying these types in accord with their biological relationships.

The early bacteriologists established a dozen genera, such as *Streptococcus*, *Sarcina*, *Bacillus*, *Bacterium*, and the like, based entirely on a few obvious morphological characters. Some of these genera are undoubtedly valid. Others like those which are based only on the presence or absence of flagella are quite as certainly invalid. No one familiar with the colon group can hold that it is reasonable to place the common type of motile colon bacillus in the genus *Bacillus* along with *B. mycoides*, *B. aerogenes*, *B. anthracis*, *B. prodigiosus*, *B. radicicola* and *B. tetani* and to place an organism having all its other properties identical but lacking flagella in the genus *Bacterium*. The same arguments hold true against the genera *Planococcus* and *Planosarcina* among the cocci. We find in several of the major groups motile and non-motile forms which are precisely alike in half a dozen respects and are clearly minor varieties of the same

type, and it is absurd to give them generic rank, and group together widely different types which are alike in no single respect except that they have flagella. These genera based on motility are on a par with a division of animals into those with wings and those without, which would place bats and birds and flying fishes and bees in one group and cats and ordinary fishes and worker ants in another.

The unsatisfactory nature of the Migula classification, which, even if the motility genera were accepted, left over one third of all known bacteria in the genus *Bacillus*, led many bacteriologists to abandon any attempt at a natural classification and to seek refuge in frankly arbitrary schematic groupings. The logical outcome of this tendency is the decimal group number which our society has adopted, the history of which has been so ably presented by Professor Harding (1910).

The group number, according to which the characters of bacteria are indicated by a conventional series of decimals, has an undoubted value and has proved a godsend to workers who study a large series of new cultures and desire a concise record of their behavior. It is a sort of index to the chief characters of the organisms in question, a method of cataloging reactions observed. It is obvious however that it is artificial, and that it does not furnish a "classification," an arrangement of bacteria according to their natural relationships.

There is some danger, I think, that this important distinction between the group number on our standard card and a real biological classification may be forgotten. When the student notes that 100 means that endospores are produced and 200 that they are not produced, he is likely to draw the conscious or subconscious conclusion that all bacteria producing endospores are more closely related to each other, are more

of a kind, than are the members of the two separate groups. I think that this is very probably a fact. Then, of the non-spore formers, he notes that strict aerobes fall under 210, strict anaerobes under 230 and facultative forms under 220. Again he is likely to draw a similar conclusion as to relative relationships and again perhaps the conclusion is reasonably correct. In the third place of the whole numbers, however, any such deduction as to natural relationships from the group number would certainly be erroneous. Of the facultative non-spore formers, all which liquefy gelatine fall under 221; and all which fail to do so under 222. That is, the group number throws together on the one hand *B. cloacæ* and the liquefying strains of fluorescent water bacteria and the liquefying proteus forms, and on the other hand *B. coli* and the non-liquefying fluorescent and proteus types. It is reasonably certain however that liquefying and non-liquefying fluorescent bacteria are more closely related to each other, that *B. coli* and *B. cloacæ* are more closely related to each other, that liquefying and non-liquefying proteus types are more closely related to each other than are the liquefying or the non-liquefying members of the three respective pairs. Precisely as in the case of Migula's motility genera the use of a single arbitrarily chosen character in classification leads to misleading results.

It is sometimes held that the difficulties we experience in bacterial classification are due to the fact that we must necessarily rely in the main on physiological rather than on morphological characteristics. I do not believe this to be the case. There is no fundamental distinction between morphological and physiological properties, since all are at bottom due to chemical differences in germ plasm, whether they happen to manifest themselves in the size and arrangement of parts or in the ability

to utilize a certain food stuff. Indeed biochemical properties have a peculiar and unique significance among the bacteria, since it is precisely along the lines of metabolism that these organisms have attained their most remarkable differentiation. The higher plants and animals have developed complex structural modifications to enable them to obtain food materials of certain limited kinds. On the other hand the bacteria have maintained themselves by acquiring the power of assimilating simple and abundant foods of varied sorts. Evolution has developed gross structure in one case without altering metabolism; it has produced a diverse metabolism in the other case, without altering gross structure. There is as wide a difference in metabolism between the pneumococci and the nitrifying bacteria as there is in structure between a liverwort and an oak. The danger in using physiological characters for classification lies, not in their inherent unreliability, but in the fact that so many physiological properties are directly adaptive in nature. Adaptive characters of similar nature are likely to arise in different groups under the influence of similar environmental conditions and may prove altogether misleading as to true phylogenetic relationships. Professor Gadov in his striking address before the British Association has called the independent evolution of a nearly identical character from homologous material isotely. We have excellent examples among the bacteria. It seems clear for example that we must assume from the presence of liquefying and non-liquefying types among so many of the principal groups of bacteria that this property has lain latent in a great many independent lines of descent and has been independently released in many of them, perhaps by environmental forces. It is particularly to avoid this danger of con-

fusing independently acquired adaptive characters with those which indicate real community of descent that we must lay stress on the significance of a number of independent characters which occur in correlation. If the correlation is due to an essential dependence of one character upon the other it is of course not particularly significant; but, when we find a number of different characters, which have no necessary connection, correlated together, the presumption is warranted that common descent is the connecting link which has united them.

It was in the study of the Coccaceæ that the full importance of emphasis on correlated characters first impressed itself upon me. It had long been the practise, following the Migula system, to group all the staphylococci of the skin and the saprophytic cocci which divide in one and two planes together in the genus *Micrococcus* and to separate the packet-formers in the genus *Sarcina*. The common cocci found on the skin, all liable to assume at times pathogenic properties, were usually classed as merely three color varieties (*aureus*, *albus* and *citreus*) of a single species *Micrococcus* or *Staphylococcus pyogenes*. In the attempt to apply statistical principles to the classification of this group,¹ Mrs. Winslow and I collected and studied 500 different strains of cocci, measuring quantitatively so far as possible eleven different characters of each strain. At once a new and surprising set of relationships manifested themselves. It was evident in the first place that on the whole the cocci living normally on the body surfaces, differed in almost every respect from the cocci

¹ First published in Biological Studies by the Pupils of William Thompson Sedgwick, June, 1906, and in the *Journal of Infectious Diseases* for the same year and later elaborated in our book on the "Systematic Relationships of the Coccaceæ," N. Y., 1908.

of the water and earth. The former usually occurred in chains or small irregular groups, reacted positively to the Gram strain, formed a meager or only fair surface growth on solid media, and produced considerable acid in carbohydrates. The cocci of the water and earth occurred in large cell groups or packets, never in chains, were usually Gram negative, grew abundantly on solid media and generally failed to ferment carbohydrates. There were exceptions of course, as there always must be in an unstable group like the bacteria. Some organisms which a general consideration of all their characters would place in the latter group were found on the skin, while others were Gram positive or fermented the sugars. Yet on the whole the relation seemed a sufficiently definite one to warrant the division of the spherical bacteria into two subfamilies, the Paracoccaceæ and the Metacoccaceæ. The next thing which was apparent was that the color of the pigment produced, instead of being a minor varietal character, was fundamentally correlated with other properties which were apparently of sufficient importance to deserve generic rank. It appeared that the orange and white staphylococci, along with the diplococci and streptococci, all shared the properties of the Paracoccaceæ just enumerated, while the yellow and red pigment formers (in spite of the occasional presence of the former on the skin and even in connection with pathological processes) exhibited the characters of the Metacoccaceæ (Fig. 4). The white and orange forms further differed from each other in the fainter surface growth of the former and in the important fact that liquefying members of the orange series liquefy twice as rapidly as do the liquefying white strains. Hence we distinguished these groups as the genera *Aurococcus* and *Albococcus*. Among the

Metacoccaceæ the yellow and red forms were sharply separated by the much higher proportion of strains which reduce nitrates to nitrites and by the absence of ammonia formation in nitrate pepton broth and by the rarity and slowness of liquefaction, among the red chromogens, for which we

FIG. 4. GROUP DIFFERENCES BETWEEN THE PARACOCCEÆ AND THE METACOCCEÆ. The upper blocks show for 221 strains of cocci whose type of chromogenesis (white or orange) would place them with the parasitic subfamily, the per cent. of strains fulfilling each of five individual criteria of that group. The lower blocks show for 279 strains of cocci whose type of chromogenesis (yellow or red) would place them with the saprophytic subfamily the per cent. of strains fulfilling each of five individual criteria of that group.

suggested the generic name *Rhodococcus*. The important point brought out by these studies was that chromogenesis and the Gram strain, characters which we all had believed to be comparatively unimportant, proved to be correlated with a number of other properties and therefore highly significant. On the other hand the Migula

distinction between *Micrococcus* and *Sarcina* appeared to be of quite minor importance. Among the yellow chromogens we found a completely parallel series of packet-formers and non-packet formers exactly alike in all other respects. So with liquefaction of gelatine. Among aurococci, albococci, micrococci and sarcinae were strains having all other properties in common, but differing in this one respect. Kligler (1913) has recently examined the cocci in the American Museum collection and has found that the fifty strains represented fall very clearly in the genera thus outlined, although he concludes that the species originally described should be modified in certain important respects.

The general principles of statistical classification were outlined as follows by Miss Rogers and myself (1906):

We have first plotted the frequency curve for each character in order to find whether the array varies about one or several modes, and where these modes are situated. . . . In the second place, we have calculated correlation factors for the most significant pairs of characters. Each mode on the curves of frequency may fairly be taken to mark a natural species or variety, and the characters which vary together must form the most important basis for the establishment of the larger groups. By such a method alone it is possible to locate those mountain peaks in the chain of bacterial variations which rightly deserve generic and specific names.

In the same year in which this paper was published, Andrewes and Horder in England presented a revision of the species in the genus *Streptococcus* (1906) based on exactly identical principles at which they had independently arrived. They say:

There was, however, one guide which, as in all such taxonomic problems, proved of the greatest help, namely, the numerical frequency of occurrence of any given type. . . . The common types stand out as mountain tops above their fellows, each mountain connected by valleys of intermediate types with many of its neighbors.

Since these suggestions were first made, the statistical method has been systematically applied by Howe (1912) to the colon group, by Stowell, Hilliard and Schlesinger (1913) to the streptococci, by Dr. Morse (1912) to the diphtheria group and by Rogers and Davis (1912) to the lactic acid groups.

There are many other serious investigations of bacterial relationships which might be cited, many of them made before the term "statistical classification" was thought of in this connection, but characterized by the fact that they include a careful comparative study of many different strains with due regard to the frequency with which types occur and to the special importance of correlated characters. Among the earlier investigations, Beijerinck's study of the acetic acid bacteria (1898), Chester's on the aerobic spore formers (1904) and Hefferan's on the red pigment producers (1904) are worthy of special mention. More recently Edson and Carpenter have given us an excellent revision of the group of fluorescent bacteria (1912). Owen (1911) has added much to our knowledge of the aerobic spore formers, White (1909) has revised the *B. bulgaricus* group and Dr. Claypole (1913) has worked out some very striking correlations between immunity relations and cultural characters among the streptothrices. The elaborate study of the dysentery group by the late Dr. Hiss (1904) and Elser and Huntoon's review of the Gram-negative cocci (1909) should also be mentioned in this connection. There has already been accumulated a considerable mass of data which when critically examined and codified should furnish a good basis for a systematic arrangement of many of the smaller bacterial groups.

So far as the general classification of the bacteria into larger groups, families and

genera, is concerned, we have also, I believe, plenty of information which if properly digested would make it possible to arrive at reasonable and helpful results. With these large groups no special statistical study is generally necessary, for the chief characters of the major types are well established. All that is needed is interpretation, but interpretation based on a view of all the available facts and on a sound conception of biological principles. Until recently the only attempt at a general classification of the bacteria based on a common-sense interpretation of all the characteristics of the organisms is that presented by Flügge (1896), the chief value of which lay in the classification of the rod-shaped bacteria into 22 groups, almost all of which appear to represent natural aggregations of allied types. For example, we all recognize that the aerobic spore formers, the anaerobic spore formers, the colon-typhoid group, the nitrifying organisms, the fluorescent bacteria, and the group of diphtheria and tubercle bacilli constitute real groups of related organisms.

Four years ago a more ambitious attempt at a fundamental analysis of the systematic relationships of the whole group of bacteria was made by Professor Orla Jensen, of the Polytechnicum of Copenhagen (1909). Professor Jensen with good reason discards the purely morphological basis of classification and in particular the distinction based on the presence or absence of flagella. The arrangement of flagella when they are present, on the other hand, offers a convenient index of other more important differences and Professor Jensen gives his two orders of bacteria the names of Cephalotrichinæ (monotrichous or lophotrichous) and Peritrichinæ (peritrichous). The Cephalotrichinæ, deriving their life energy almost entirely from oxidative processes, are all water or

moist earth forms, with the exception of a few peculiar plant and animal parasites and for the most part grow badly or not at all on ordinary organic media, and spores are never formed. The series begins with the Oxydobacteriaceæ, including the most primitive bacteria, which oxidize methane and carbon monoxid, the nitrifiers, the acetic acid bacteria and the Azotobacter group. Then follows the Actinomyces family which includes the root nodule bacteria and the mycobacterium (tuberculosis) group. The collocation of the latter forms is startling at first, but their morphology, their oxygen requirements and their unique pathological relations, almost symbiotic by contrast with the quick toxic action of other pathogenic bacteria, offer some evidence of real relationship. The third, fourth and fifth families are the Thiobacteriaceæ (the sulfur bacteria), the Rhodobacteriaceæ (the red or purple sulfur bacteria) and the Trichobacteriaceæ (*Claadothrix*, *Crenothrix*, *Beggiatoa*, etc.) which are clearly natural groups. The last two families, the Luminibacteriaceæ and the Reducibacteriaceæ, are typically denitrifying organisms which form a connecting link between the primitive oxidizing bacteria and the Peritrichinæ. They include the fluorescent water bacteria and the phosphorescent vibrios and at the higher end of the series such forms as the cholera organism in which the ability to split complex products with the formation of lactic acid and indol begins to appear.

The second order, the Peritrichinæ, includes the more specialized bacteria in whose metabolism the splitting of carbohydrates or amino-acids plays a primary rôle rather than oxidation or denitrification. They are rods or cocci, peritrichous when possessing flagella at all, and among them are found all the commoner putrefactive and parasitic types. This order, according

to Jensen, may be divided into four families: The first, the Acidobacteriaceæ, includes the non-spore-forming carbohydrate fermenting types, among the principal representatives being the colon-typhoid group and practically all the cocci. His second family, the Alkalibacteriaceæ, shows a higher development of the power of decomposing nitrogenous bodies, and includes the liquefying proteus forms, the actively liquefying aerobic spore formers and certain urea fermenters. The last two families, the Butyribacteriaceæ and the Putribacteriaceæ, are made up of the strict anaerobes.

Whatever minor criticisms may be made of Professor Jensen's scheme, I believe that no one who has thought seriously about bacterial relationships can study it carefully without feeling that it is by far the most successful attempt yet made at a real biological classification of the group and that future progress will probably consist in its modification and extension rather than in any profound reversal of its basic principles.

Inertia in terminology is strong and it is the business of no one in particular to criticize and report on the value of suggestions as to bacterial classification and nomenclature. We are all too busy with our own special field to undertake such a task of our own accord. Yet I believe that in the present state of bacteriology such a critical examination of suggested systematic arrangements is most essential. A mass of work has been done in the last ten years, potentially valuable, but almost useless so long as it remains a sealed book to all but its respective authors and their pupils.

What we need at this time is a court of appeal on matters of systematic bacteriology, a court to which all suggested classifications, past and future, may be referred

for official acceptance or rejection, in whole or in part. Such a court or commission might take first Professor Jensen's classification as the most recent comprehensive attempt to treat the whole group of the bacteria, and after careful consideration might adopt such of his families and genera as seem well established and issue a report in which they should be definitely and clearly defined. Such a report from a commission of a proper caliber would not be ignored as work of any single worker may be, but would be adopted and would become at once a part of the practical working machinery of our science. The genera and species suggested for the Coccaceæ, the Andrewes and Horder species of the genus *Streptococcus*, Chester's species of spore-bearing aerobes, Dr. Morse's types of pseudo-diphtheria bacilli, Edson's types of fluorescent bacteria, etc., might be later taken up so that ultimately a complete scheme of bacterial classification would be at our disposal.

Such authoritative commissions on classification and nomenclature are well established in the older biological sciences, as for example, the International Commission on Zoological Nomenclature appointed by the Third International Zoological Congress in 1895 and made permanent at the Fourth Congress in 1898. Its work has been much more along the line of precise legal definitions and the determination of priority in terminology, than would be the case with a similar commission in bacteriology. The broader constructive work which has already been accomplished in zoology still remains for us to do. Furthermore we have no international congress to which such a commission could profitably report on all the phases of its work, although for one group of the bacteria, the colon-typhoid group, a commission on systematic relations was created by the last International

Congress on Hygiene and Demography, of which Dr. Weber, of Berlin, is chairman and the president and two past presidents of this society are the American members. I believe this to be a fitting time for a more far-reaching attempt to criticize and collate and systematize the work which has been done in many countries and by many observers on the characterization and classification of bacterial types. The inception of such a plan may very properly come from the Society of American Bacteriologists which through its standard card has already done so much for the development of the purely descriptive side of our science. As a practical outcome of this long survey of the problems of systematic bacteriology, with which you have borne so patiently, I suggest that we invite fifteen bacteriologists from the principal scientific countries to act as an international commission on the characterization and classification of bacterial types, with the general objects outlined above. If you should approve this plan, and if we can secure the cooperation of investigators of the first rank (as I have no doubt will be the case), I believe that we can thus render to bacteriology a great practical service, worthy of the highest aims which our society has held in view.

- patient work by Dr. Frederick C. Ferry, dean and professor of mathematics in Williams College. His tables give the registration of students taking various subjects of study in eighteen American colleges and universities. These subjects are commonly divided into three groups, roughly determined by the nature of the topics included. Thus, group I. may be called the "language group"; group II., the "humanities group"; and group III., the "science group." The distribution of work in each of these groups in any given college affords some indication of the popularity of the group. To express this distribution it is necessary to give, as Dean Ferry has done, for each subject the number of "student hours of instruction." In view of the great variation in total attendance at different colleges Dean Ferry has reduced his figures to percentages, on a semester basis, limiting them to undergraduates in the academic college.

On examining Dean Ferry's tables the present writer perceived the possibility of making the comparisons somewhat more pointed, and of securing a fair representation of popularity not only for groups but for separate subjects of study. A "student-hour of instruction" may be interpreted to mean one hour per week in the classroom, taken by one student throughout one semester. The actual work done includes an estimated pair of hours spent in study in preparation for the work of the classroom. This estimate is often not realized, the student taking his chances of escaping a test, especially if the class is rather large. Two or three hours in the laboratory are hence fairly counted as the equivalent of one hour in the classroom. Let h denote the value in student-hours for a given course; for example, if the student has 3 meetings per week in the classroom and 2 afternoons per week in the laboratory, then $h = 5$. Let n denote the number of students taking this course during a given semester; then nh denotes the work done in this course.

Now, let $\Sigma(nh)$ denote the work done in the sum of all the courses of a given subject; for example, there may be four courses in physics. Let A denote the whole academic work in stu-

ACADEMIC STUDENT ELECTIONS

IN SCIENCE, October 24, 1913, are some interesting tables exhibiting the results of much

dent hours done in all subjects in the college during a semester. Then the quotient of $\Sigma(nh)$ by A yields a percentage, p , that expresses the numerical demand for this special subject by the students, on the assumption that there is freedom of election of studies. Various local considerations apart from the nature of the subject are often operative in determining the student's election; such as the personal popularity of the professor and the reputation of his courses for ease or difficulty. English, for example, may be a "soft snap" under one professor and a formidable stumbling block under another. The evils connected with freedom of election, especially for freshmen and sophomores, are increasingly appreciated by educators; so that the assumption of unlimited freedom is now, happily, not quite warranted.

for a semester. If the value of p for a selected subject is found in eighteen or twenty different colleges, the average of these values may be expressed by P . This average will of course be affected with enough uncertainty to be expressed as an integer. Thus, if the numerical popularity of French comes out as 8.74, and of physics as 4.37, the corresponding percentages would be taken as 9 and 4, respectively; indicating that out of the work done in these colleges about 9 per cent. may be expected to be in French, and about 4 per cent. in physics; or that the popularity of French is more than double that of physics, though the exact numerical results, 8.74 and 4.37, would seem to indicate an exact ratio of 2 to 1, which has to be taken with some grains of allowance.

TABLE OF PERCENTAGES

	<i>p</i> (max.)		<i>P</i>	<i>p</i> (min.)	
GROUP I.:					
Greek.....	Yale,	3.91	2	Wisconsin,	0.41
Latin.....	Bryn Mawr,	12.87	5	Harvard,	1.89

100.00					

But the student who aims at a bachelor's degree finds himself often put to the necessity of choosing between what he regards as evils. By taking an average of such elections in a considerable number of colleges the personal element is to some extent eliminated.

The percentage, p , is obviously a rate, substantially the same for an annual session as

In the accompanying table these integral percentages are given in the middle column, as the result of studying Dean Ferry's tables. To show the range of variation the maximum and minimum values of p are additionally tabulated, along with the names of the corresponding institutions. Thus, the popularity of Greek is greatest at Yale and least at Wis-

consin. Nearly 4 per cent. of the academic work at Yale is in Greek, while at Wisconsin it is less than half of one per cent. The general popularity of this subject in the eighteen institutions compared is seen to be 2 per cent. The eighteen institutions selected by Dean Ferry are Amherst, Bowdoin, Bryn Mawr, Columbia, Cornell, Dartmouth, Harvard, Johns Hopkins, Mount Holyoke, Oberlin, Princeton, Smith, Stanford, Wellesley, Wesleyan, Williams, Wisconsin and Yale.

In making out the present table a number of subjects of small popularity have been excluded, such as Sanskrit, Slavic languages, archeology, anthropology, art, music, Semitics, Egyptology, veterinary science, history of science, etc. Their total value is 3 per cent., so that the sum of the recorded work for column *P* is 97 instead of 100; but, for each subject included, the value of *P* was made out on the basis of 100. The total for group I., as recorded in Dean Ferry's table, is seen to be 24.50 instead of 24; for group II., 46.78 instead of 47; for group III., 28.72 instead of 26. It will be noted that everywhere the tendency seems to be for students to crowd their work into group II., the amount of work taken in this group being nearly as great as in both of the other groups put together. Apart from the interesting humanistic character of the subjects included, they are wholly free from the intricacies of grammar and especially of mathematics.

English naturally leads in importance, with 16 per cent.; and mathematics, in spite of its rigors, presents 8 per cent. These high rates are partly accounted for by the fact that in most, if not all, American colleges these two subjects are prescribed, at least for freshmen; so that here the assumption of freedom of election is in large measure to be discarded.

For the 16 subjects represented in the table, with total value 97, the average percentage obtained by dividing 97 by 16 is a little over 6. This number may hence be taken as a rough standard for comparing the student demand for different subjects; or, for the average extent to which a subject may be studied, whether prescribed or elected. This

average of 6 per cent. is not reached by astronomy, Greek, geology, physics, Bible, Latin, political science or biology. It is reached by philosophy and chemistry. It is exceeded by economics, Germanic languages, mathematics, Romance languages, history and English.

The table shows that the study of astronomy, so nearly universal in the senior classes of American colleges two generations ago, has now nearly vanished, being only half as much pursued as that of Greek; and this in turn was a subject of the first importance among our grandfathers. The popularity of astronomy is expressed by 1.87 at Mount Holyoke, a woman's college, where the teaching of this subject seems to be conducted with much pedagogic skill. It is least at Wisconsin, where the percentage number is only 0.11, despite the fact that the professor in charge, a man of international reputation, has done much original work.

Geology, a department of science which, as taught in our colleges, can not be compared with astronomy in mathematical difficulty, seems to maintain in these a degree of popularity about the same as that of Greek, 2 per cent., or one third of that of chemistry and of philosophy.

Physics and Bible study are apparently of equal popularity, about half of that of mathematics, and two thirds of that of chemistry. The demand for Bible study is by far greatest in institutions for women. It is expressed by 8.01 at Wellesley; 6.62 at Mount Holyoke; 5.88 at Oberlin. It is only 0.21 at Yale, where Y. M. C. A. influence is most widely diffused and voluntary attendance on morning chapel exercises throughout the annual session is maintained by popular demand. It is only 0.06 at Princeton, the presbyterian stronghold, which is fortified additionally by the power of the adjacent theological seminary.

The average percentages just discussed should be interpreted only as variables which indicate the modern academic trend. The range of variation for the particular list of colleges compared is worth noting in the first and last columns of the table. In every indi-

vidual college it may be expected that local influences will produce marked deviations from the indications of the table. But, none the less, the figures seem to be of enough educational value to be published.

W. LE CONTE STEVENS

WASHINGTON AND LEE UNIVERSITY,
December 24, 1913

SCIENTIFIC NOTES AND NEWS

PROFESSOR THEODORE RICHARDS, of Harvard University, has been elected president of the American Chemical Society for the year 1914. M. T. Bogert and A. D. Little have been elected directors and C. H. Herty, Julius Stieglitz, L. H. Baekeland and W. L. Dudley councillors-at-large for a three-year period.

PROFESSOR R. S. WOODWORTH, of Columbia University, was elected president of the American Psychological Association at the recent New Haven meeting. Professor R. M. Ogden, of the University of Tennessee, was elected secretary for a three-year period.

At the recent Princeton meetings, Dr. George F. Becker, of the U. S. Geological Survey, was elected president of the Geological Society of America, and Professor A. P. Brigham, of Colgate University, was elected president of the American Society of Geographers.

THE Society of American Bacteriologists, at its Montreal meeting, elected Professor Charles E. Marshall, of Amherst, to the presidency and Professor F. C. Harrison, of MacDonald College, to the vice presidency.

It is proposed to present to the Royal Society a portrait of the retiring president, Sir Archibald Geikie, the distinguished geologist. A committee, with Sir William Ramsay as chairman, has been formed to collect subscriptions, which it is agreed should not exceed three guineas.

PROFESSOR W. B. SCOTT, of Princeton University, and Professor E. L. Trouessart, of Paris, corresponding members of the Zoological Society of London, have been elected foreign members of the society. Professor E. Ehlers, Göttingen, Mr. J. H. Fleming, To-

ronto, and Dr. C. Gordon Hewitt, Ottawa, have been elected corresponding members of the society.

DR. ALBERT ERNEST JENKS, professor of anthropology in the University of Minnesota, has been granted leave of absence from the university the second semester of the current year. Certain aspects of ethnic amalgamation, and environmental influence will be given field study. He will spend February and March in the southern part of the United States, and the next five months in Europe and northern Africa.

At a meeting of the State Geological Commission of Oklahoma late in December, the resignation of D. W. Ohern as director of the Oklahoma Geological Survey was accepted. L. C. Snider, the assistant director, declined to consider the directorship and C. W. Shannon, field geologist, was appointed director. The personnel of the scientific staff of the Survey as now constituted is as follows: C. W. Shannon, A.B., A.M. (Indiana), director; L. C. Snider, A.B., A.M. (Indiana), assistant director; L. E. Trout, A.B., A.M. (Oklahoma), field geologist; Wm. A. Buttram, A.B. (Oklahoma), chemist.

A SERIES of three lectures has been planned for the classes of blind children that visit the American Museum of Natural History. In the first of these on December 18, Admiral Robert E. Peary recounted some of the experiences of his memorable Arctic journey which resulted in the attainment of the North Pole.

THE Herter Lectures of the University and Bellevue Hospital Medical College will be given during the week beginning January 12, 1914, at Carnegie Laboratory, 338 East 26th Street, New York City. Professor Sven Hedin will lecture on "Colloids and their Relation to Biological Chemistry."

At a recent meeting of the Abernethian Society at St. Bartholomew's Hospital, London, Sir William Osler delivered an address on "The Medical Clinic—a Retrospect and a Forecast."

PROFESSOR E. M. EAST, of Harvard University, delivered in December a lecture entitled

"The Improvement of Plants by Hybridization" before a joint meeting of the "Garden Association" and the Horticultural Society of Newport, R. I.

At the Dropsie College for Hebrew and Cognate Learning, Philadelphia, Dr. Ignaz Zollschan, of Vienna, will deliver three lectures on January 14, 15 and 19 on "The Cultural Value of the Jewish Race," "The Significance of the Mixed Marriage" and "Tendencies of Economic Development Among the Jewish People."

The Journal of the American Medical Association states that on December 11, the day on which he would have completed his seventieth year, there was instituted a quiet memorial in memory of Robert Koch by Professor Loeffler, the present director of the Institute for Infectious Diseases in Berlin, in the Robert Koch mausoleum. The entire board of directors of the Robert Koch foundation for the campaign against tuberculosis took part in the celebration. Memorial wreaths were placed in the mausoleum by this as well as other corporations, and in honor of the memorial day the *Deutsche medizinische Wochenschrift*, the regular organ of publication of the great bacteriologist, issued a special number to which interesting contributions were furnished by the most noted pupils of Robert Koch, Loeffler, Ehrlich, Brieger, H. Kossel, Uhlenhuth, Pfeiffer, Kolle and others.

SIR JOHN BATTY TUKE, Unionist member for Edinburgh and St. Andrews Universities 1900-1910, the authority on mental diseases, left to the Royal College of Physicians, Edinburgh his bust by John Hutchison.

It is proposed to place a tablet suitably inscribed to commemorate Benjamin Franklin in the Church of St. Bartholomew the Great, West Smithfield—the parish in which he worked as a printer. Subscriptions for this memorial may be sent to Mr. E. A. Webb, 60 Bartholomew Close, London, E.C.

PROFESSOR WINSLOW UPTON, head of the astronomical department of Brown University, and director of the Ladd Observatory, died on January 8, aged sixty-one years.

THE twelfth general meeting of the Association of Economic Biologists was held at Liverpool on December 30 and 31.

DR. TEMPEST ANDERSON, known for his studies of volcanoes, has left £50,000 to the Yorkshire Philosophical Society, of which he was formerly president, and £20,000 to the Percy Sladen Memorial Fund, established by his sister, Mrs. Sladen, in 1904.

THE family of the late Dr. Javal, the distinguished ophthalmologist, has given to the Eye Clinic of the Paris Hôtel-Dieu the fine library which he had collected in his ophthalmological laboratory at the École des Hautes Études in the Sorbonne. Madame Javal has completed the large collection of French and foreign periodicals up to the end of 1913.

SIR ARTHUR EVANS has, as we learn from *Nature*, presented to the museum at Cambridge the last instalment of an interesting set of objects selected from the collections of his father, the late Sir John Evans. The gift consists of 121 specimens ranging in date from prehistoric times to the eighteenth century. The value of the collection is greatly enhanced by the fact that all the specimens composing it were found in Cambridgeshire and the adjacent counties.

In the alcove of the North American archeology hall of the American Museum of Natural History a mural series has recently been completed. It consists of five polychrome frescoes, three of which are enlarged copies of the frescoes on the walls of the cavern of Font-de-Gaume in France and two are enlarged copies from the ceiling of Altamir in Spain. The originals of these represent paleolithic art at its highest point of perfection. The copies were made by Mr. Albert Operti.

DR. CARLOS DE LA TORRE of the University of Havana, Cuba, has made a very interesting and valuable addition to the collection of conchology in the department of invertebrate zoology. This material was secured by Dr. F. E. Lutz in his recent visit to Cuba and consists of land shells, many of which are described by Dr. La Torre.

THE faculty of medicine of Harvard University offers a course of free public lectures, to be given at the Medical School, on Sunday afternoons, beginning January 4, and ending May 10, 1914. The lectures, which begin at four o'clock, are as follows:

January 4. "Recent Studies of the Bodily Effects of Fear and Rage," by Dr. W. B. Cannon.

January 11. "Rational Infant Feeding," by Dr. John Lovett Morse.

January 18. "The Effects of Habits of Posture upon Health," by Dr. J. E. Goldthwait.

January 25. "The Tumors and Diseases of the Breast." (To women only.) By Dr. R. B. Greenough.

February 1. "Some Surgical Diseases of Childhood and their Causes," by Dr. J. S. Stone.

February 8. "Adenoids and Tonsils," by Dr. A. Coolidge, Jr.

February 15. "Microscopical Mechanisms of the Brain," by Dr. Charles S. Minot.

February 22. "Some Causes of Nervous Instability," by Dr. E. W. Taylor.

March 1. "Tooth Preservation in Children and Adults," by Dr. William P. Cooke.

March 8. "Skin Nostrums," by Dr. Charles J. White.

March 15. "Chairs, Backache and Curved Spine," by Dr. E. H. Bradford.

March 22. "Spectacles and Eye-glasses; their Use and Abuse," by Dr. Charles H. Williams.

March 29. "Diet in Relation to Diseases of the Kidney," by Dr. E. P. Joslin.

April 5. "Aid for the Deaf," by Dr. Clarence J. Blake.

April 12. "Eugenics versus Cacogenics," by Dr. E. E. Southard.

April 19. "The Hygiene of Pregnancy." (To women only.) By Dr. F. S. Newell.

April 26. "The Diagnosis and Immediate Treatment of Lesser Injuries, including the Use and Abuse of Antiseptics," by Dr. J. Bapst Blake.

May 3. "Arterio Sclerosis," by Dr. W. H. Smith.

May 10. "The Sexual Instinct; its Use and Abuse." (To men only.) By Dr. E. H. Nichols.

THE following are the principal prizes, as we learn from the *British Medical Journal*, awarded by the Paris Academy of Medicine this year. The Louis Boggio prize (triennial, of the value of £172) has been given to M. H. Vallée, director of the Veterinary School of

Alfort, for his researches on the prevention and cure of tuberculosis. The Adrien Buisson prize (triennial, of the value of £420), for the discovery of means of cure of diseases considered incurable, has been awarded to Dr. Dopfer, professor in the École d'Application of the military health service, for his work on epidemic cerebro-spinal meningitis, the meningococcus, antimeningococcic serum, parameningococci, and antiparameningococcic serum. The Cheillon prize (£60), for the best work on the treatment of cancer, has been awarded to Dr. R. Robinson, of Paris, for his account of a method of biochemical diagnosis of cancerous affections. The Herpin (of Geneva) prize, for the best work on epilepsy and nervous diseases, has been awarded to Dr. André Barbé, of Paris, for his study of secondary (bulbo-protuberant and medullary) disease of the pyramidal bundle. The Laborie prize (£200), for the greatest progress in surgery, has been given to Dr. Guizez, of Paris, for his work on broncho-esophagoscopy. The Meynot prize (£104), for the best work on diseases of the eye, has been awarded to Dr. F. Bourdier, of Paris, for his essay on the optic meninges and primary optic meningitis. The Roger prize (quinquennial, of the value of £100), for the best work on diseases of children, has been given to Professor E. Weill, of Lyons, for his book, "Précis de médecine infantile." The Tarnier prize (£120), for the best work on gynecology, has been awarded to Drs. P. Puech, of Montpellier, and J. Vanverts, of Lille, for their book, "Tumors of the Ovary and Pregnancy." The Tremblay prize (quinquennial, of the value of £284), for the best work on urinary diseases, has been awarded to Dr. E. Papin, of Paris, for an essay on the sexual functions and prostatectomy. Among the principal prizes of the Académie des Sciences are the Montyon prize in medicine and surgery; three, each of the value of £100, have been awarded to Madame Lina Negri Luzani, of Paris, for studies on the corpuscles, which, in conjunction with her late husband, she discovered in the nervous system of mad dogs; to Dr. L. Ambard, of Paris, for his

memoir on the renal secretion; and to M. A. Railliet, G. Moussu, and M. A. Henry, for their researches on the etiology, prophylaxis, and treatment of the distomiasis of ruminants. The Bréant prize has been divided as follows: Three prizes, of the value of £80 each, have been awarded to Dr. C. Levaditi, of Paris, for his researches on acute epidemic poliomyelitis and acute infectious pemphigus; to Drs. A. Netter and R. Debré, of Paris, for an essay on cerebro-spinal meningitis; and to Professor V. Babès, of Bucharest, for his treatise on rabies.

THE production of pig iron in 1912 was 33,802,685 tons of 2,000 pounds each; that of platinum was 1.3 tons. The value of the iron per ton was \$12.44, as against \$1,328,391 per ton for the platinum. For the sake of convenient comparison and because in commercial practise the various ores and metals are measured by a variety of units such as the long, short and metric ton, flask, airoirdupois pound and troy ounce, the United States Geological Survey has issued a short summary of the "Production of Metals and Metallic Ores in 1911 and 1912," stated in terms of the short ton of 2,000 pounds, much of which, however, is derived from imported ores, bullion, etc. A comparison of the production of some of the better known metals is as follows:

	Quantity	Value
Platinum.....	1.304	\$ 1,732,221
Gold.....	188,108	113,415,510
Silver.....	4,471.4	80,187,317
Aluminum.....	32,803	15,089,380
Quicksilver.....	939.9	1,057,180
Nickel.....	22,421	17,936,800
Tin.....	8.4	8,850
Copper.....	734,052	242,337,160

THOUGH at one time in the early history of the country an average of 6,000 maple trees were destroyed in clearing the ordinary New York or Pennsylvania farm, maple is to-day, according to the department of agriculture, one of the most widely used and valuable native hardwoods. A bulletin on the uses of maple, just issued by the department, states that the wood finds place in an enormous number of articles in daily use, from rolling pins to pianos and organs. It is one of the best

woods for flooring, and is always a favorite material for the floors of roller skating rinks and bowling alleys. It leads all other woods as a material for shoe lasts, the demand for which in Massachusetts alone exceeds 13 million board feet annually. Sugar maple stands near the top of the list of furniture woods in this country. The so-called "bird's-eye" effect, the department explains, is probably due to buds which for some reason can not force their way through the bark, but which remain just beneath it year after year. The young wood is disturbed each succeeding season by the presence of the bud and grows around it in fantastic forms which are exposed when the saw cuts through the abnormal growth. Maple, the department goes on to say, is one of the chief woods used for agricultural implements and farm machinery, being so employed because of its strength and hardness. All kinds of wooden ware are made of maple, which holds important rank also in the manufacture of shuttles, spools and bobbins. It competes with black gum for first place in the manufacture of rollers of many kinds, from those employed in house moving to the less massive ones used on lawn-mowers. Athletic goods, school supplies, brush backs, pulleys, type cases and crutches are a few of the other articles for which maple is in demand. Seven species of maple grow in the United States, of which sugar maple, sometimes called hard maple, is the most important. The total cut of maple in the United States annually amounts to about 1,150,000,000 feet. Nearly one half is produced by Michigan, with Wisconsin, Pennsylvania, New York and West Virginia following in the order named. Sugar maple, says the department, is in little danger of disappearing from the American forests, for it is a strong, vigorous, aggressive tree, and though not a fast grower, is able to hold its own. In Michigan it is not unusual for maple to take possession of land from which pine or hardwoods have been cut clean, and from New England westward through the Lake States and southward to the Ohio and Potomac rivers few other species are oftener seen in woodlots.

ON the eastern edge of the campus of the Ohio State University rises a new building of white stone, the new museum of the Ohio State Archeological and Historical Society, which is to house the Indian relics and treasures of the mound builders which make Ohio the richest field of pre-historic remains in the United States. With the first week of the New Year the collections will be moved from their old home in Page Hall to their beautiful new building. The structure itself is as nearly fireproof as man can make it, utilizing stone, steel and concrete, with no wood used in its construction. Almost all the furniture is made of steel and the entire library and offices are similarly built. The exhibition rooms are entirely of mahogany as steel cases are impracticable. It is planned to have a formal opening in January, with appropriate exercises and public inspection of the rare collections housed in the building, appropriations for which were authorized at a recent session of the Legislature. Professor G. Frederick Wright, of Oberlin, is president of the society and Professor W. C. Mills, of Columbus, its curator.

At the recent meeting of the American Ornithologists' Union in New York City, as we learn from *The Auk*, the advisability of changing the time of meetings from fall to spring was considered. This innovation was favored for two principal reasons: First, to make it possible for those members to attend who, for business or other reasons, were unable to leave home in the autumn. Second, members residing on the Pacific Coast are very anxious that the stated meeting in 1915 be held in San Francisco while the World's Panama-Pacific Exposition is in progress. It was the consensus of opinion that spring was the most favorable time to hold this meeting and to successfully carry out the plan, it was thought advisable to allow at least a year to intervene between the Washington and San Francisco meetings. This would give members throughout the country ample time to plan in advance for the journey across the continent. In this connection it is to be remembered that the expense of the transconti-

ental trip will be greatly reduced if a considerable number of members and their friends attend. With the above plan in mind, the Committee of Arrangements has decided to name Easter week, beginning with April 6, 1914, as the best time for the Washington meeting.

UNIVERSITY AND EDUCATIONAL NEWS

THE late Right Hon. G. W. Palmer bequeathed £10,000 to University College, Reading, and it is now announced that Mr. Alfred Palmer has suggested that this legacy should be devoted to building a university library, and on behalf of Mrs. G. W. Palmer, his sisters, and himself, has offered to supplement it to such extent as will be necessary to enable a suitable library to be built on the site reserved for the purpose, and also to provide an endowment fund for maintenance.

GOLD HALL, a dormitory of the group of original buildings at the Connecticut Agricultural College, was burned to the ground on January 4, with a loss of \$10,000.

THE Stevens Institute of Technology announces that, beginning with the year 1914, admission to its freshman class will be either by certificate or examination. Students will be admitted to the freshman class on certificates from secondary schools which have been placed upon the accepted list by the faculty.

THE civil engineering department of the engineering college of the University of Illinois offers a two weeks' course, January 19-31, to aid the newly appointed county superintendents of highways in preparing for their duties. In this the university will be aided by the state highway commission, whose engineer will be one of the leading speakers. The work is in charge of Professor Ira O. Baker, head of the department of civil engineering. The ceramics department offers a course, January 12-24. It is open to all who are engaged in factory operations. The process of clay testing, preparation, molding, drying, burning and decorating are to be treated. The work will be under the direction of R. T. Stull, acting director of the department, and Professor A. V. Bleininger, ceramic chemist, Bu-

reau of Standards, Pittsburgh, Pa. The agricultural department offers this year, January 19-31, some new courses in forge work and carpentry. These courses will under the immediate charge of Director Benedict, of the mechanical engineering department.

At the Massachusetts Institute of Technology Dr. H. O. Taylor has been appointed to be research associate in the research laboratory of electrical engineering, and Francis Byron Morton to be assistant in physics, in place of F. I. Hunt, resigned.

At Vassar College Dr. Elizabeth B. Cowley, instructor in mathematics, has been made assistant professor of mathematics.

The governors of the Imperial College of Science and Technology have constituted two new chairs of chemistry, and appointed two new professors—Dr. Jocelyn Field Thorpe, professor of organic chemistry, and Dr. James C. Philip, professor of physical chemistry.

DISCUSSION AND CORRESPONDENCE

ON THE IDENTITY OF VERRUGA AND CARRION'S FEVER

We are indebted to Dr. Richard P. Strong, of the Harvard Medical School, for reopening the question of the unity or duality of Carrion's fever and eruptive verruga, so termed. Assisted by Dr. E. E. Tyzzer, he carried out an interesting series of experiments at the bacteriological laboratory of the Institute of Hygiene in Lima, from June to August, 1913, in cooperation with Dr. Júlio C. Gastiaturú, the director of that laboratory. Some of the details of the results obtained were presented to the Fifth Latin American Medical Congress in Lima by Dr. Gastiaturú on November 14, 1913, causing a great sensation in Peruvian medical circles. It is not too much to say that this announcement has fallen like a thunderbolt in Lima. The thorough probing of the problem which will undoubtedly follow swiftly upon this reopening of the case will certainly bring the truth to the surface and settle the matter with finality. From the entomological and protozoological points of view, as well as from such clinical and other

points of view as present themselves to the writer, the following data seem to bear definitely upon this subject.

Reasons why Carrion's fever and eruptive verruga (so-called) are respectively malignant and benign forms of one disease:

1. They have identically the same geographical distribution so far as known.

2. They are connected by every possible gradation of clinical symptoms.

3. The bone pains which are characteristic of the benign form often occur with marked severity associated with such high temperatures that the case must be diagnosed as malignant or Carrion's fever rather than benign or eruptive verruga (so-called).

4. Carrion's fever is always followed by the eruption, usually of the miliar but sometimes of the nodular type, the latter being more distinctive of the benign form of the disease, this indicating the identity of the malignant and benign forms etiologically.

5. Infection by *Phlebotomus verrucarum* from the same locality produces both in both man and laboratory animals, sometimes giving rise to one and sometimes to the other, apparently according to the severity of the infection due to the number of the infective *Phlebotomus* concerned or to the degree of resistance of the host infected.

6. The bodies named *Bartonella bacilliforme* by Strong and Gastiaturú are present in both, their abundance being apparently in direct ratio to the degree of fever exhibited at any time in any given case of either, and they disappear from the peripheral circulation of both immediately before the appearance of the eruption, though they may return if the course of the eruption be interrupted by pyrexial relapse, disappearing finally on the definite and uninterrupted sequence of the eruption.

7. The bodies *Bartonella bacilliforme* are quite evidently not organisms, but changes wrought in the red cells by the activities of the as yet undiscovered verruga organism, these changes evidently being effected in the bone marrow, as evidenced by the fact that the more abundant the *Bartonella* bodies are the

more abundant are normoblasts, megaloblasts and other abnormal red cells in the peripheral circulation.

8. Neither Carrion's fever nor verruga eruption can be produced in either man or laboratory animals by the injection of blood containing the *Barton* bodies alone, but both can be produced in man by injection of the virus from the human eruption, and the benign form can be produced in laboratory animals by such injection, the reason why the acute form has not been similarly produced being that either the animals are far less susceptible to the disease than man or the toxicity of the virus becomes attenuated for them after running its course in man, though experience indicates that it may yet be so produced in monkeys if not in other animals.

9. The pathologic microorganisms transmitted by *Phlebotomus* in all parts of the world so far as known invariably set up an initial fever stage of longer or shorter duration and greater or less intensity, and verruga eruption is in every case preceded by some degree of pyrexia, though sometimes so slight as to be hardly noticeable.

10. The eruption following Carrion's fever as well as the eruption preceded by mild fever or an almost unappreciable degree of fever both show a marked tendency to appear first at the sites of inoculation by the *Phlebotomus* and to become most pronounced at such sites.

11. Cases of eruption following either often if not always confer immunity against both.

12. *Phlebotomus verrucarum* gets its infection certainly from some reservoir, probably one of the native mammals, but whether from the lower mammals or man it is practically certain that the reservoir of infection supplies but one kind of microbe capable of developing in and being transmitted by the carrier.

13. Both are amenable to the same treatment so far as this has been determined for either.

All of the above facts have been verified by the writer's work and experience during his investigation of verruga transmission in the verruga zones and in the laboratory. Severe pyrexia has resulted in a *Cebus capuchinus*

from the bites of the *Phlebotomus*, the rectal temperature passing 43° C. and the red cells showing the *Barton* bodies. Miliar eruption succeeded. The *Barton* bodies have also been found by the writer in the red cells of dog, rabbit and guinea-pig inoculated with the *Phlebotomus*. Eruption away from site of inoculation has been produced in a hairless dog by hypodermic injection of over 400 *Phlebotomus* in five lots, mashed up in physiological solution. Upon the excision of a large nodule, another has grown in its place. The writer's assistant in the verruga work, Mr. George E. Nicholson, is in the hospital with verruga, the result of 55 bites by *Phlebotomus* September 17 last at Verrugas Canyon, due to inadvertently getting his hands in contact with the net while asleep. His symptoms have been high fever with severe bone pains, and a large number of *Barton* bodies in the red cells. Details of the experiments with laboratory animals will shortly be presented, including blood and tissue studies, temperatures and weights, with illustrations.

Almost any one of the above reasons, taken by itself, would seem to indicate conclusively the unity of verruga. If Dr. Strong's thesis can be made to harmonize with all of these facts, then it is possible that he is right, but the indications seem to point strongly the other way.

VERRUGA LABORATORY,
CHOSICA, PERU,
November 17, 1913

SCIENTIFIC BOOKS

Scott's Last Expedition. Vol. I., being the Journals of CAPTAIN R. F. SCOTT, R.N., C.V.O. Vol. II., being the Reports of the Journeys and the Scientific Work undertaken by DR. E. A. WILSON and the surviving members of the Expedition. Arranged by LEONARD HUXLEY, with a preface by SIR CLEMENTS R. MARKHAM, K.C.B., F.R.S. With 18 colored plates, 260 full-page and smaller illustrations. New York. Dodd, Mead and Company, 1913. Large 8vo. 2 vols. xxiv + 443, xiv + 376 pp. 8 maps. \$10.00 net.

It is many years, if ever, since the civilized world has been so stirred into homage to courage and to sympathy for disaster, as were displayed when the ocean cables spread over the globe the fateful story of Scott's Last Expedition, which is now told in these beautiful volumes. Suffice it to say that the detailed record shows high planes of project and of action, which should ensure to Commander Evans and his surviving associates scarcely less honor and credit than is given so fittingly to Scott and his heroic dead.

That recognized polar authority, Sir Clements R. Markham, outlines the aims and scope of Scott's expedition as the "completion and extension of his former discoveries," especially of "fossils, which would throw light on the former history of the great mountains," which bound the south-polar plateau. For this work Scott had "the most completely equipped expedition for scientific purposes connected with the polar regions, both as regards men and material," and "a fuller complement of geologists, biologists, physicists and surveyors than ever before composed the staff of a polar expedition." Science was the primary aim, so that Scott had removed the taint of commercialism, which caused Milton to qualify his praise of the quest of a northern route to China by saying it "might have seemed almost heroic if any higher end than excessive love of gain and traffic had animated the design." Thus a twentieth-century sailor attained the seventeenth century ideal of heroism.

Referring briefly to the south-polar journey, it is clear that Scott's plans were perfected and carried out with striking ability. Despite a season of unprecedented severity as to blizzards and cold, the party would have survived but for other misfortunes. These were the inability to originally occupy Cape Crozier as a base, owing to ice-conditions; the breakdown and loss of motor sledges; and especially the deep, soft snow that fell during the four-day blizzard at Beardmore glacier on the outward journey. Later came the death of Evans from crevasse-injuries and sastrugi-falls, and the freezing of heroic Oates, which followed close on the time lost and delays caused by geologi-

cal work, a primary aim be it remembered. Let the readers of SCIENCE bear in mind that these men perished indirectly as martyrs to a sense of scientific duty. The day spent in collecting the fossil volumes that may tell the story of past geological history, and the strength consumed in dragging these specimens, nearly forty pounds in weight, exhausted the fatal limit of time and so sealed their fate. Yet no word is uttered suggestive of abandoning their harrowing load, over frightful mazes of sastrugi and of glacier.

This is not the place to dwell on the ideals of courage, of devotion, of unselfishness, which ran like the King's red thread through the warp and woof of their expeditionary duties—of the living as well of the dead. Their recital moves the hearts of the present, and will serve as exemplars to stir the souls of the future.

Storm-bound and crevasse-injured, the southern party perished to a man within eleven miles of safety, while ending a sledge journey of more than sixteen hundred miles,—unprecedented for its length in polar annals. As to conditions which prevented that short march to food and fuel, they had for the ten previous days traveled in temperatures averaging sixty-eight degrees below freezing (this in March, *our September*), and were enveloped in a blinding blizzard, which lasted continuously for eight days.

In these transcripts from Scott's diary are no words of adverse criticism when he received the astounding news that a rival was in the field,—for south-polar travel only be it noted. Amundsen's route being shorter, foreseeing the probability of being forestalled at the pole, Scott recalls with becoming dignity of soul the scientific scope of his work in the sober statement, on September 10, 1911, that "nothing, not even the priority at the Pole, can prevent the expedition ranking as one of the most important that ever entered the polar regions."

Severe as were the physical experiences of the south-polar party in their dramatic explorations, they entailed relatively less bodily discomfort and acute suffering than did the midwinter journey for strictly scientific pur-

poses to the penguin rookery at Cape Crozier. The object of the trip was to secure eggs of the emperor penguin—a species most nearly approaching the primitive form of bird—at such stages of early embryos as might make clear the development of the emperors. A journey in midwinter was necessary as the singular emperor penguin is perhaps unique in nesting at the coldest season of the year—in temperatures approximating one hundred degrees below the freezing point of water.

Apart from the weather the trip involved sledge travel of two hundred miles in almost complete darkness, wherein the party must cross the crevassed "barrier" and finally pass through the chaotic pressure-ridges of the shore-impinging sea floes. The journey was made without disaster, and three eggs brought safely home, but this scientific work tested humanity to the utmost. The outward march was made in eighteen days with an average temperature of minus forty degrees—that of frozen mercury. Only once did the temperature rise to zero Fahr., and a minimum of one hundred and nine degrees below freezing was experienced. A violent blizzard, in which an hourly wind velocity of 84 miles was recorded at the home station, blew away their tent and unroofed their hut. Exposed to the fury of the storm they were forty-eight hours without food, uncertain of their fate. They finally recovered their tent, without which they must have perished, for the blizzard temperature of -24° fell steadily to -66° Fahr. For science and not for fame was made a trip unsurpassed as to the severity of cold and violence of storm successfully endured by a field party.

The scientific appendices to these volumes are brief and tentative, as would naturally be expected. Full of thrilling interest and of importance are the accounts of the journeys made for the physiographic and geological explorations of the coast regions of northeastern South Victoria Land. The enforced wintering of Campbell's party, equipped for summer travel only, was on the verge of disaster several times. Wintering in a hut carved out of a snow-covered glacier, they lived for nine months from hand to mouth on penguins and

seals. Other scientists had experiences but little less dangerous and trying. Indeed it may be said that no previous polar expedition has ever surpassed that of Scott in the devotion of its staff to scientific investigations entailing personal, prolonged and perilous service.

Brief chapters treat of scientific work, such as that wonderful survival of the condition of the Ice Age—the so-called barrier of Ross; the physiography and glacial geology of South Victoria, supplemented by a geological history of that ice-clad region; fossils connected with coal-beds, and those thought to be suited to settle the controversy as to the nature of the connection of Australia and Antarctica; and as to ice physics. Meteorology, tides, magnetism, pendulum work, and atmospheric electricity are treated, though incompletely, while the local sea-work is supplemented by a summary of the biological investigations carried on by the *Terra Nova* in her voyages from 1910 to 1913. Volcanic investigations were pursued on Mt. Erebus, and fossil evidences were obtained from the Great Beacon Sandstone Series.

No previous volumes of polar narrative have been so fully and appropriately illustrated as this thrilling story of the work of Scott's Last Expedition, largely due to Dr. Wilson and Mr. Pointing. Not only do the illustrations please the artistic sense, but many will also be of permanent value to scientific students. This is especially true of the photographic plates showing glacial conditions, and the many beautiful reproductions of snow and ice forms. Nor can one neglect those of birds and seals, of mountains and clouds, and even of blizzards. Among the 278 full-page plates will be found some which will convey ampler and clearer ideas to experts than does the written word.

The editorial supervision must have been hasty, for there are many slips and the text is overburdened—detracting from the dignity of the narrative. The main map is most unsatisfactory. Oates Land does not appear thereon. It is an offence to Americans that not only is Wilkes Land omitted from the key map, but it

has been replaced by King George V. Land; patriotic but a sad blunder.

The appreciation accorded to the Scott expedition excites reflections as to the contrasting attitude of the United States and of European governments towards scientific work that is neither commercialized nor exploited. Strikingly similar in aims, in accomplishment and in fateful disaster were the Lady Franklin Bay International Polar Expedition and Scott's Last Expedition. The former—a governmental enterprise—penuriously fitted, its scientific work largely entrusted to enlisted men—who were actuated largely by love of science—occupied the post of honor and of danger of the eleven cooperating nations. It contributed to a hitherto unequalled degree to arctic hydrography, meteorology, pendulum work and magnetism. Yet its complete success in its scientific purposes, as well as in field-work absolutely free from disaster, was formally requited neither by the government nor by any scientific societies of the United States. It took years of effort on the part of its chief to even obtain the meager lawful allowances and the pitiful pensions.

The English expedition, lavishly equipped, had 7 officers and 12 scientists, whose efforts also increase to a very large degree our scientific knowledge of Antarctica. Its heroic personnel win titles of nobility, promotions and the highest scientific honors, while the public contributed hundreds of thousands of dollars to meet adequately and generously all expeditionary requirements—both material and memorial.

The failure of our government to properly recognize scientific work appears to be due to an antiquated and inherited national policy, which must be to the ultimate detriment of the common weal. This year the attention of the government has been urgently called to untoward conditions, arising from illiberal treatment of expert officials. Distinguished chiefs of several important national bureaus officially report increasing difficulty in maintaining an efficient scientific staff. Unusual and steadily augmenting numbers of scientists and experts are accepting commercial posi-

tions in order to meet the enhanced cost of living.

While American admiration for the Scott expedition was so great that we materially aided in the raising of the memorial fund, our energies should also be employed in urging the adequate recognition of those scientific and professional officials, on whose skill, judgment, and patriotism the future of the democratic government in the western hemisphere must so largely rest.

A. W. GREELY

Probleme der physiologischen und pathologischen Chemie. Fünfzig Vorlesungen über neuere Ergebnisse und Richtungslinien der Forschung für Studierende, Ärzte, Biologen und Chemiker. By DR. OTTO VON FÜRTH. II. Band: Stoffwechsellehre. Leipzig, Verlag von F. C. W. Vogel, 1913. Pp. xiv + 717.

The only occasion for adding anything to the favorable impression of Professor von Fürth's lectures which the reviewer has already expressed¹ in reference to the first volume lies in the fact that the newer collection deals with a more specific group of topics: metabolism. The author's underlying plan consists in starting with the nutrients at the very beginning of the alimentary processes and in following the foodstuffs, as far as present knowledge permits, on their travels through the organism to the places where the final derivatives disappear in the unexplored depths of intermediary metabolism. To this is added a discussion of the nature of those ultimate stages of this physiological function which are characterized by the combustion of the food fragments in the living organism. In pursuance of the foregoing scheme the chemistry and physiology of digestion and absorption are reviewed in the light of those newer contributions which take cognizance of the special conditions that pertain in the alimentary canal, with its unique innervation and secretory interrelations.

The attitude of the critic to a contribution like the present one—a book giving evidence on every page of the remarkable familiarity of

¹ See SCIENCE, 1912,

the author with the enormous modern literature of chemical physiology and his sympathy with a treatment of its problems less narrow than is current in many quarters—can not be determined by the same criteria that apply to text-books or laboratory manuals. Von Fürth's lectures make no pretense to systematic formulation of routine topics; they offer something far more stimulating to the advanced student, namely, viewpoints to guide him, and goals to be reached. The limitations of our present knowledge are frankly pointed out. What could be more satisfying than this (freely translated) incidental confession of the author in presenting the subject of purine physiology:

"The sum total of the available observations is so vast that no honorable person, even if he devoted years of effort to this topic alone, could maintain that he had delved into the ultimate depths of the subject and fully mastered it. Yet how perverted it would be if I, who have not devoted myself permanently to this field, were simply to traverse it hastily, contenting myself with a few dogmatic statements. Bear in mind that I am merely attempting, in so far as my efforts permit me to appreciate it, to present to you a picture of this world of phenomena; and do not forget that this picture would appear different to other eyes. It is a human privilege to see the things of the external world with our own eyes; but we must not deceive ourselves into forgetting that it is, after all, a subjective point of view that we take."

Here, as in the first volume, there are personal touches and subjective impressions that lend a sort of enlivening color to the treatment of topics that the usual writer is apt to present in a stereotyped fashion. A few quotations may serve to illustrate what is here meant. The reviewer can not conceal his satisfaction in reading the following:

"Man hat sich vielfach bemüht, die moderne Entfaltung der physikalischen Chemie auch dem Probleme der Salzsäurebildung im Magensaft dienstbar zu machen. Als seinerzeit die Ionenlehre langsam in die biologischen Disziplinen einzusickern begann, konnte man

vielfach die Beobachtung machen, dass eine Übersetzung einer Fragestellung in die Sprache der Ionenlehre mit einer Erklärung verwechselt wurde. Heute ist man sich wohl ziemlich im Klaren darüber, dass, wenn ein Problem in noch so gelehrter Weise mit dem grösseren Publikum schwer verständlichen Fachausdrücken umschrieben wird, man seiner Erklärung nicht näher kommt, als wenn man dasselbe etwa in spanischer oder russischer Sprache formuliert. Leider ist hie und da ein Restchen der Bemühungen mittelalterlicher Magister, durch möglichste Schwerverständlichkeit ihrer hochgelehrten Darstellungen ihrem Auditorium nur so recht zu imponieren, auch noch in der modernen Wissenschaft (insbesondere in der medizinischen) zu verspüren" (p. 10).

The author's attitude toward many open questions is expressed in the concluding sentence of a discussion of the purpose of the complete digestion of proteins to amino acids.

"Dass aber ein Individuum, trotzdem es die allerverschiedensten Proteinsubstanzen mit seiner Nahrung aufnimmt, stets und unter allen Umständen und sein ganzes Leben lang die Spezifität seiner körpereigenen Eiweisskörper in allerstengster Weise zu wahren vermag, kann ich nur so verstehen und begreifen, dass ich mir vorstelle, jeder Eiweisskörper der Nahrung werde vor der Assimilation sehr wahrscheinlich bis zu den Aminosäuren desintegriert. Doch ist das eine durchaus subjektive Meinung, die ich Sie nur als solche hinzunehmen bitte. Schliesslich kann ja jeder Mensch nur mit seinem eigenen Kopfe denken" (p. 73).

Similarly at the end of an excellent review of the theories of gout, in which he champions Wiechowski's views, von Fürth remarks:

"Es ist mir wohl bekannt, dass andere diese Dinge anders beurteilen;—aber, wie ich schon früher einmal sagte: jeder Mensch kann nur mit seinen eigenen Augen sehen und mit seinem eigenen Kopfe denken. Glücklicherweise kommt jedes naturwissenschaftliche Problem früher oder später in ein Stadium, wo allen subjektiven Auffassungen ein natürliches Ende gesetzt ist und der objektive Sachverhalt

als etwas Selbstverständliches erscheint" (p. 171).

The welcome touches of humor creep in here and there, as in the following conclusion:

"Dagegen ist die Frage der Herkunft endo- und exogener Harnpurine, nachdem allerdings ganze Ströme von Tinte für sie geflossen sind, immerhin so weit gediehen, dass sie (—und das ist immer ein gutes Zeichen—) eigentlich mit wenigen Worten erledigt werden kann" (p. 150).

Again:

"Es macht nun den Eindruck, dass dieses (bisher wenig beachtete) Moment einer beim Gichtiker gesteigerten Affinität der Gewebe der Harnsäure gegenüber dem Kerne des Gichtproblems näher steht, als z. B. die Frage der Harnsäurebindung im Blute, welche so viel Staub aufgewirbelt hat, und mit der wir uns jetzt auch notgedrungen ein wenig beschäftigen müssen" (p. 175).

And in advising a liberal intake of water in gout the author recognizes that he is merely repeating the dicta of empirical practise. Hence he reflects:

"Es wäre hier, wie überall, durchaus unangebracht und verkehrt, wenn wir das, was nüchterne und objektive Beobachter mit ehrlichem Bemühen bei jahrzehntelanger Beobachtung für zweckmässig befunden haben, einfach ignorieren wollten, weil wir dafür keine theoretische Erklärung zu finden wissen. Vergessen wir nie, dass die Beobachtungen richtig und die Theorien falsch sein können und dass ein richtiger Naturforscher die ersteren im allgemeinen höher bewertet als die letzteren. Nur ist das objektive Beobachten insbesondere bei der Therapie chronischer innerer Erkrankungen leider eine unendlich schwierige Sache, daher dieselbe zu allen Zeiten und bei allen Völkern das gelobte Land der wissentlichen und unwissentlichen Charlatanerie war und sein wird" (p. 190).

The admonition to caution, on the other hand, in rejecting the suggestions of science is brought out in a discussion of Friedenthal's proposal to render the common vegetables more readily available in the nutrition of man. Von Fürth writes:

"Der Wunsch, Menschen zu Gras- und Blätterfressern zu machen, mag Ihnen vielleicht auf den ersten Blick recht lächerlich erscheinen. Vergessen Sie aber nicht, dass es nicht immer die schlechtesten Errungenschaften des Menschengeschlechtes waren, (—ich erinnere Sie an die Dampfmaschine, das Leuchtgas und die Elektrizität—), welche in ihren ersten Anfängen von der Mehrzahl der Zeitgenossen nur von der humoristischen Seite aufgefasst worden sind. Vielleicht stehen wir hier vor einer jener Möglichkeiten, das Dasein späterer Generationen leichter zu gestalten, als es den jetzt Lebenden zuteil geworden ist" (pp. 480–481).

It is of little value to refer here to the details of a book so replete with up-to-date information and so readable at the same time. A typical specimen of the care and comprehensiveness with which the facts have been collected and reviewed is furnished by the discussion of the rôle of muscle in glycolysis. The entire story is told from the early work of Cohnheim, through the critique of Embden and his coworkers, to the latest constructive criticism of Levene and Meyer. An example of the intelligent reconciliation of conflicting views is exhibited in the discussion of the origin of endogenous urinary purines:

"Wir werden uns daher bemühen, uns von jeder einseitigen Auffassung fernzuhalten und weder die Leukozyten, noch die Muskeln, noch die Tätigkeit der Verdauungsdrüsen oder Nieren für die endogene Harnsäurebildung ausschliesslich verantwortlich machen, dieselbe vielmehr als den Ausdruck einer jederzeit und in allen Geweben sich vollziehenden Zellabnutzung betrachten" (p. 151).

Von Fürth is at his best in the discussion of the special features of alimentation and the intermediary metabolic phenomena. His treatment of the problems and methods of general metabolism—the balance of matter and energy—is far less detailed, yet always timely. The unbiased attitude is nowhere better shown than in the comments on the status of the much debated questions of the protein minimum in human nutrition and the theories of protein metabolism:

"Es sind dies eben Dinge, die sich wirklich gegenwärtig nicht, ohne gegen das Postulat der Objektivität zu sündigen, mit wenigen Worten abtun lassen. Ein Blick auf Casparis Literaturverzeichnis, das mehr als ein halbes Tausend Abhandlungen umfasst, wird Ihnen zeigen, dass ich darin recht tue" (pp. 475-476).

In conclusion the reviewer is tempted further to quote the judgment of von Fürth respecting the duty of an investigator to correlate his own experiences so that they afford a logical summary of his undertaking. Thus in referring to the myriad of details published in recent years by London and his pupils on the physiology and chemistry of the digestive functions von Fürth remarks:

"Ich bin ehrlich genug, um offen einzugehen, dass ich mich einer Würdigung dieser ungeheuren Fülle von sicherlich sehr verdienstvollen Einzelbeobachtungen nicht gewachsen fühle. Eine solche wird wohl erst dann möglich sein, wenn London selbst sich einmal der Mühe unterzieht, dieselben im Zusammenhange kritisch zu verarbeiten und seine leitenden Gedanken, die auf so viele Publikationen verteilt sind, dass der Aussenstehende den Zusammenhang verlieren muss, hervorzuheben. Es ist dann zu hoffen, dass sich aus diesen und anderen Arbeiten, welche verwandten Zielen zustreben allmählich ein abgerundetes Bild des Eiweissabbaues im Darne in seinen einzelnen Phasen gestalten wird" (p. 71).

To those who wish to orient themselves in the changing aspects of physiological research, particularly its chemical manifestations, the lectures by von Fürth will surely serve as a stimulating guide. Books of this type are rare.

LAFAYETTE B. MENDEL

SHEFFIELD SCIENTIFIC SCHOOL,
NEW HAVEN, CONNECTICUT

Alternating Currents and Alternating Current Machinery. By D. C. and J. P. JACKSON. New York, The Macmillan Company, 1913. Pp. viii + 968, 521 text figures. Price, \$5.50.

This new edition of a well-known work furnishes one of the best general treatments on the subject of alternating currents, as did the first edition in 1896. Rewritten and expanded

to twice its former size, it forms a very complete and, on the whole, well-balanced treatise. The work is attractive, the style easy and the illustrations, many of them diagrammatic, are instructive. Descriptive and mathematical discussions are combined throughout, and examples from practise are used to illustrate theory.

Attempting to cover so much in a single volume assigns a formidable task to both author and reader. Although on the whole satisfactory, the treatment might to advantage have been made more systematic; the book would not have suffered by being more condensed. The chapters on synchronous machines (185 pages) and on transformers (155 pages) approach special treatises on these subjects. The latter would be improved by complete rearrangement, the discussion of mutual induction forming not so suitable an introduction to the transformer, in a book of this kind, as would a discussion of diagrams and equivalent transformer circuits that are discussed later in the chapter. The discussion of power and power factor is particularly satisfactory and complete.

That the authors omitted many historical footnotes seems unfortunate. Such notes not only serve to give credit where it may be due, but they make possible for the reader a more detailed study of special subjects than the limited description of any one text will permit. The footnotes retained (and these are not a few) prove their value. The authors refer in their preface to the intentional omission of many notes on the ground that they are unessential for undergraduates. But the scope of the book justifies no such limitation; its field is much wider than the undergraduate class-room. The book should find many readers whose undergraduate days have long since passed. The authors are to be thanked for its production.

FREDERICK BEDELL

CORNELL UNIVERSITY

Petrographisches Vademekum. Second edition. By E. WEINSCHENK. Freiburg im Breisgau and Saint Louis, Mo., Herder Pub-

lishing Company. 1913. Pp. viii+210; 1 plate; 101 figures in text. Price, ninety cents.

This little volume presents in an interesting manner those facts concerning rocks which are of interest to the student of general geology. The author has in mind a pocket manual which may be of service in the field. The treatment is from the standpoint of the macroscopic properties of rocks and is thoroughly modern. The book is well printed. The illustrations are excellent.

UNIVERSITY OF MICHIGAN

SPECIAL ARTICLES

THE CULTIVATION OF TISSUES FROM THE FROG

In a series of experiments on the culture *in vitro* of tissues of the frog it was found that several kinds of tissues show a marked outgrowth after being kept for a few days in lymph or plasma. Small pieces of the tissues were mounted according to the usual method in hanging drops of the culture medium and sealed with vaseline in hollow slides. Cells may remain alive under these conditions for several weeks.

Spleen, bone-marrow and pseudothyroid give rise to a fringe of outwandering cells resembling leucocytes which extend farther and farther into the surrounding medium. Larger connective tissue cells wander out later, and both types of cells exhibit amœboid changes. Small pieces of tissue may almost entirely disintegrate into wandering cells.

The epithelial cells of the skin extend generally as a broad thin sheet of tissue. The cells move out in contact with the cover slip or the lower surface of the drop. Individual cells of the epidermis may become isolated and creep out alone, but there is a marked tendency for the cells to keep together in a continuous membrane. In a previous paper on the movements of the ectodermic epithelium of amphibian larvæ¹ it was shown that the ectoderm cells actively creep out by an amœboid movement of

the very thin and transparent protoplasm of their free borders. The method by which sheets of epithelium extend in the adult frog is essentially the same as in the embryo or larva.

In several cases black pigment cells were seen to isolate themselves and wander out along the cover slip or lower surface film of the drop. In some cases, especially in the smaller pigment cells, the changes in form were fairly rapid. Pseudopods were thrust out and retracted very much as in the common amœba, and in some instances the cells were seen to migrate nearly across the field of the microscope. The processes of the pigment cells of the adult, unlike those of the larvæ, may be nearly transparent, and they usually are so when first formed; frequently, however, they are very soon invaded by pigment granules. Outwandering cells may show branching processes characteristic of the expanded melanophores of the frog's skin. The change in form of the pigmented mass within the cell is due in part to changes in the outline of the whole cell and in part to the flowing back and forth of pigment granules within the cell processes. There is a measure of truth, therefore, in both the rival theories of the changes of the chromatophores in the skin of the frog.

In some preparations the peritoneal epithelium wandered out in the form of a sheet of tissue considerably greater in area than the original preparation. For the most part the extension consisted of flattened cells arranged in a single layer and showing a hexagonal contour like the cells of the shed cuticle. Many of these cells were furnished with cilia which beat actively for two weeks. The ciliated cells frequently became amœboid and wandered free from the rest, sending out fine processes several times the original diameter of the cell. Sometimes the processes branched repeatedly. One would not suspect these cells to be derived from ciliated epithelium were it not for their tuft of beating cilia, and the fact that one can actually observe their transformations. Follicle cells of the testis may creep out and give the appearance of giant amœbæ.

Fuller details of the behavior of various

¹ Univ. of Calif. Pubs. Zool., 1913.

types of tissue cells will appear in later papers. Similar experiments were tried with the tissues of crayfishes and crabs with little result beyond keeping these cells alive for several weeks. The blood corpuscles of the crayfish were kept alive and active for three months.

S. J. HOLMES

NOTE ON THE ABSORPTION OF CALCIUM DURING
THE MOLTING OF THE BLUE CRAB,
CALLINECTES SAPIDUS

THE problem of molting in crabs has thus far been investigated, with one exception,¹ only from the morphological point of view.² The following observations bear on certain chemical phases of the process of hardening following normal molting in the common blue crab.

The crab hardens by the deposition of CaCO_3 within the tissues of the soft shell. Has this Ca been absorbed and held in reserve during the period of preparation for molting,³ or is it absorbed from the sea-water during the actual period of hardening? To test this matter, the following procedure was employed. Three pairs of crabs were chosen, each pair consisting of a recently shed individual and of a hard-shell individual of nearly the same size.⁴ A comparison of the Ca content of the individuals of the same pair should throw light on the alternatives suggested. If the Ca content of the two members of each pair is equal, then the Ca must be absorbed before molting and held in reserve. If the Ca content of the hard specimen is very much larger than that of the soft, then the Ca must be absorbed after

¹ Irvine and Woodhead, *Proc. Roy. Soc. Edinb.*, Vol. 16, pp. 324-354, 1888-89.

² For a review of the literature on the natural history of molting in Crustacea, see Herrick, Bull. U. S. Bureau of Fisheries, Vol. XV., pp. 1-252, 1895. For this species of crab, see Hay, App. Rep. U. S. Comm. Fish., pp. 395-413, 1904.

³ Cf. Smith, *Quart. Journ. Microsc. Sci.*, Vol. 59, p. 272, 1913.

⁴ These were collected at the Beaufort, N. C., station of the U. S. Bureau of Fisheries. The writer is indebted to Dr. H. M. Smith, the commissioner, for the privilege of staying at the station.

molting. Furthermore, if the first alternative is the true one, the Ca content of a crab in the act of casting its shell should be much greater than that of a normal hard crab. If, however, they have the same Ca content, then the second alternative is indicated.

Each crab was ashed separately, and the Ca in the ash determined by precipitating it as the oxalate, igniting and weighing as the oxide. The results of the analyses are indicated in the table. In each pair the hard-shell specimen contains about twenty times the amount of Ca contained in the soft one. Also, Crab No. 9, which was in the act of casting its shell, has a Ca content comparable to that of a normal hard individual.

This shows clearly that the Ca used by the soft-shell crab for the purpose of hardening its new shell is not present at the time of the molt, but is absorbed from the sea-water during the hardening.

The mechanism by means of which a molting crab is enabled to absorb such abnormally large quantities of Ca is at present obscure, and in view of the meager data at hand, a discussion of this problem is best postponed until more work shall have been done.

TABLE

Crab No.	Condition	Width, Cm.	Weight, Gm.	Weight, Ca, Gm.	Ca Content, Per Cent.
6	soft	8.3	37.20	0.0720	0.19
11	hard	8.3	34.54	1.845	5.34
3	soft	9.7	56.53	0.1468	0.26
7	hard	9.5	61.62	2.963	4.81
13	soft	10.5	70.00	0.2197	0.31
12	hard	11.0	70.90	3.617	5.17
8	hard	8.7	54.75	2.861	5.22
9	molting	8.5 ⁵	67.93	2.520	3.72

SELIG HECHT

BIOLOGICAL LABORATORIES,
THE COLLEGE OF THE CITY OF NEW YORK

⁵ The width of the new shell was 9.8 cm. The per cent. of Ca in this specimen is low because the molting crab weighed more than an ordinary 8.5 cm. crab, and also because the old shell had two legs missing, which were being regenerated. The actual weight of Ca, however, is very close to that of a normal hard crab.

SOCIETIES AND ACADEMIES

THE BOTANICAL SOCIETY OF WASHINGTON

THE ninety-second regular meeting of the Botanical Society was held at the Powhatan Hotel on Tuesday evening, December 2, 1913, at which a dinner and special program were given in honor of the seventieth birthday of Dr. Edward Lee Greene, the president, Dr. C. L. Shear, presiding.

Mr. John H. Parker was elected to membership.

The program was as follows:

Personal Experiences: MR. FREDERICK V. COVILLE.

Mr. Coville related incidents in connection with his first meeting with Dr. Greene at the Madison Botanical Congress in 1893, and expressed a high appreciation of his work, particularly of his "Landmarks of Botanical History."

Berkeleyan Days: MR. V. K. CHESTNUT.

Mr. Chestnut spoke of his student days at the University of California and of the inspiration received from Dr. Greene by his botanical students.

Botanical Writings: PROFESSOR A. S. HITCHCOCK.

Professor Hitchcock recalled at the International Botanical Congress in 1893 at Madison an incident as illustrating Dr. Greene's taxonomic methods. One day he showed to a group of interested botanists a difference between the two common species of foxtail grass, *Chaetochloa viridis* and *C. glauca*. He pointed out that the blades of the first were straight, while those of the second were twisted into a partial spiral. He stated that the reason why these differences were not given in the books was partly from tradition, it not being considered good form to depart very widely from the system of basing differences on the characters of the flowers or fruit; and partly for the reason that the botanists who wrote the books were not sufficiently familiar with the growing plants.

Dr. Greene's first taxonomic paper¹ was entitled "Notes on Certain Silkweeds."

Professor Hitchcock stated that the value of Dr. Greene's contributions to botany or his influence upon botanical thought did not rest solely upon the large number of new species he had described, but that he had studied many groups of plants, had revised many genera, discussed relationships and set on their feet, as it were, species and genera of early authors that had been relegated to oblivion by those that followed.

Reminiscences: MR. IVAR TIDESTROM.

Mr. Tidestrom stated that Dr. Greene began his

botanical career before the Civil War. In 1862, while a young soldier of nineteen in the army of General Grant, he collected a number of plants from the battlefield of Fort Donelson. This collection he sent to his mother, who had them mounted in an album and exhibited at a fair of the Sanitary Commission at Chicago. The collection was sold for \$50 and the money applied for the relief of sick and wounded soldiers.

Dr. Greene, after all the jealousies and personalities have disappeared, should be remembered not for the many species he has diagnosed, but for his unchallenged devotion to botany, for the gathering of an herbarium of nearly 100,000 specimens, and a library of some 3,600 volumes.

Mr. Tidestrom then stated that a few botanists knew the plants of their regions better than any one else, but challenged any one to produce a man who could approach Dr. Greene in the knowledge of plants of the vast empire lying between New York and San Francisco.

Rocky Mountain Flora: PROFESSOR AVEN NELSON.

"I count it singularly fortunate that this interesting event should have happened to occur during my short stay in Washington. I feel doubly delighted in that I am permitted not only to express my personal pleasure by my presence but also to voice for others, as well as myself, the high regard with which we greet the man whom to-night we delight to honor.

"The third part of a great continent, the interior west; the Rocky Mountain region of America, brings its greetings of good-will and love to him to whom its floral wealth is an open book. To every working botanist in this vast field the name of our guest is a familiar word. It matters not whether he be devoted to the technical or the applied phases of the subject at some point in his work every botanist finds the taxonomist's services required. I therefore presume to speak for my colleagues in every experiment station, college and university from Mexico to Manitoba and westward to the sea; and not for my colleagues only but for every amateur who loves the wayside flower for its own sake, as well as for that larger public that loves the woods and fields for their beauty and for their bountiful products. These all send greetings and grateful acknowledgment of the help and pleasure conferred upon them.

"For more than forty years Dr. Greene has loved the plants of the west with a love born of sympathetic, first-hand companionship. To the seemingly barren saline deserts, the chaparral-covered hills, the grassy parks, the dense forests and

¹ Bot. Gaz., 5: 64, 1880.

the alpine heights he is no stranger. Could he leave his more serious tasks long enough he would hasten to greet the floral friends of that earlier day as well as to renew his fatherly interest in the hundreds of plant children of his maturer years. When Edward L. Greene first began tramping over the plains, racing through the valleys, or eagerly climbing the unknown heights of Colorado and Wyoming your speaker was still a small boy on an Iowa brush farm. Little did I then think as, plowing corn with old Dobbin, I stopped to pick the cockle-burs from between the toes of my bare feet, that some day I too should be vitally interested in strange and beautiful plants in a, to me, unknown land. But to my friend and teacher (for such I count him in the largest and best sense) they had even then become of absorbing interest. He was gathering specimens in order that he might know the splendid treasures that greeted him at every turn.

"This man, a missionary, in rounding up and corraling for a life of decency and usefulness, the cowboys of the then 'wild and woolly' west, traveled far and wide. He sought men in the open marts and plants in their secluded nooks. The offerings he brought back to the altar were both acceptable, but may it not be that, reversing the order of that primal day, the flowers and fruits of the field yielded more acceptable incense than the firstlings of the flock? I imagine that as the years sped by, he more and more taught men of the wisdom and goodness of the Creator through the marvelous adaptations and beauty of the flora.

"As preaching is teaching and teaching is preaching, so the transition to the professor's chair was an easy one. During the years as they were slipping along, his field of observation widened, his knowledge of plants and their characters deepened, and his theory of the principles of classification ripened. Thus he has gradually been brought into the zenith of his power. Plants from the east and the west, from the north and the south have passed under his observation, but no field has received such discriminating scrutiny as the Rocky Mountains. He knows this field piecemeal; he knows it as a whole.

"And what a flora it is! Some of the states have singly almost as many species as the whole empire east of the Missouri. Environments of greatest diversity as to soil character, water content, heat and light factors, and all these interacting upon each other as they are successively modified by altitudes varying from near sea-level to

alpine heights have given a flora that is marvelous in its complexity. Near relatives of species well fixed under normal and uniform conditions seem here to have been thrown into such a state of 'wobble' that new forms appear to have arisen over night. Multitudinous variations, more or less well fixed, crowd upon each other everywhere. Decry species-making as you will, in the west nature seems to have been working overtime at this very thing and in a very abandon of joy. Then why should not her greater children who have the eyes to see and the mind with which to discern read and record the results?

"In this work Dr. Greene holds and has long held an enviable place. The intimate field knowledge of the earlier decades of his career forms the basis for the discriminating work that is now the marvel and the despair of those of us who have drunk less deeply at the Pierian spring. As we note his facile pen, the classical clearness, brevity and exactness of his diction, the rapier-like thrusts of his criticism, that cut but carry no toxins, one can not help feeling that for a botanist to know little Latin and less Greek is a misfortune—may almost a crime. Sometimes such an one must wonder whether

"Twere better to have loved and lost
Than never to have loved at all."

"For our crass ignorance he has scourged us again and again. Though the lash may 'cut to the quick' yet by these stripes are we being healed. They were never meant to drive a man from the field simply because he is a beginner. Dr. Greene always has a word of encouragement for him who enters Flora's temple to worship in the right spirit. He manifests no desire to preempt the place and the 'divine right' of the king is not engraved upon his banner.

"That other eyes fail to see the things that he sees; that even from similar observations different judgments are formed and different conclusions drawn are not to him of such serious moment that each may not go on with friendship for the other, each cultivating his own wee bit of the ever-widening field. To live honestly with nature, to deal justly with your fellow worker, to love mercy is a creed to which we can all subscribe. Were this not true and generally practised, few there be that would dare to follow nature in her devious paths. No single mind can grasp all her secrets. Truth is always truth but she is many-sided. No one pair of eyes can view her from all sides at any one time. A partial truth may in effect, there-

fore, be a complete error, hence error often rides in honesty's carriage.

"Differ as we may as to what constitutes a species, the object of us all is to know plants and to help others to know them. To know and to use plants that they may contribute to our wealth is well; to know them that they may contribute to the health and pleasure of body and mind is better; to know them that we may read a few of God's thoughts after him and thus enrich our souls is best. He who puts us in closer touch with the Creator through his creations is doing a man's work in God's world.

"In conclusion let me say that we have not met to place wreaths upon the brow of our distinguished coworker. There are none which his splendid achievements in systematic, historical and philosophical botany have not already won. His head is already resplendent with a silvery crown. The white is not the frost of many winters. It is the incarnation of the spirit of beauty and service that finds its best expression in spring-time flowers and autumnal fruitage. New radiance is gained at every passing milestone. May there still be many of them. May all the years bring seed-time and harvest in which the fruitage shall be as abundant as in the seven years typified by the seven well-favored, fat-fleshed kine that Pharaoh saw in his dream—fruitage even unto well-filled ears upon every stalk. May no lean kine nor blasted ears devour any of the beautiful years in the life of him who is seventy years young to-night."

Response: DR. GREENE.

Dr. Greene, after expressing his appreciation of the honor accorded him by the Botanical Society, related a few interesting incidents connected with his life.

His first vague impressions were connected with flowers, of roses and geraniums in his mother's window, at the early age of a year and a half. When he was a boy eight years of age the people in the district in which he lived frequently would go to him to find out the names of plants and where certain rare ones could be found.

One of the most interesting incidents that he related was a journey on foot from San Diego, California, to Santa Fé, New Mexico, in the year 1877, when there was not a line of railroad in all southern California, and only a stage line from San Diego to Santa Fé. Before starting out on this venturesome journey he visited the old cemetery at the San Diego Mission. He said that he

had always loved old graveyards and cloudy weather, and that music with a minor strain appealed to him especially. Among the black crosses in the graveyard was a white marble slab bearing the inscription "Edward L. Greene," with the dates of his birth and death. He who had borne this name had died at Dr. Greene's own age at that time. Dr. Greene wondered if this could be an omen, and whether it meant that he was starting out upon his last journey.

The country from San Diego to Yuma was a difficult one, and he carried only his portfolio and a few changes of socks, sending his money ahead in post office orders. At Yuma he met with a cordial reception, and was invited to hold religious services the next morning after his arrival in a public hall. He remained there over Sunday and Monday. Afterwards he saw in the little newspaper published at Yuma the following notice, concise and to the point in the expressive language of the frontier: "Last Saturday evening the Reverend Edward L. Greene reached Yuma on foot from San Diego. On Sunday morning he preached an excellent sermon to a fair congregation, and another in the evening to a large one. On Tuesday morning, refusing all offers of transportation or financial help, he continued his way eastward. This is solid pluck in big chunks. Boys, get acquainted with him; you will like him, and will find that he is no chicken-eating bummer."

The first Indians he encountered on this journey were standing in a clump of *Covillea* bushes looking at him curiously. Being rather apprehensive, he walked straight to them and fearlessly seized the arms of one of them as though inviting him to wrestle. This Indian, a very tall young man of splendid physique, noticed a ring on Dr. Greene's finger, a ring of red Australian gold. He asked if it were real gold. Dr. Greene took it off his finger and handed it to him, thinking that he would never see it again, but the Indian, after tossing it up and catching it once or twice as if to test its weight, handed the ring back to him.

Dr. Greene reached Silver City in April and remained there three months collecting plants in all directions within a radius of several miles. The only botanist who had preceded him in this locality was Dr. Charles Wright, whose collections had made it classic ground. On one excursion Dr. Greene discovered a beautiful valley about forty miles from Silver City. It was most picturesque and contained cold and hot springs. When he

returned to the nearest settlement he described the marvelous beauty of this valley. A short while afterwards some of his friends, attracted to the valley by his description, camped in the same spot. They were all murdered there by Indians.

On his journey from Silver City to Santa Fé Dr. Greene was overtaken by a man on horseback, an agreeable-looking fellow, dressed in a business suit. He carried two pistols and a rifle slung over his shoulder. At the first stage station the two travelers stayed over night. The stranger seemed to be interested in Dr. Greene and his work. He was a fair-spoken, likable man, with polished manners. Dr. Greene noticed that he carried great rolls of greenbacks bulging from his pockets. Dr. Greene carried about 15 or 20 dollars of his own in a bag swung over his back. The two travelers proceeded onward the next day together. On the road the stranger asked Dr. Greene if he had ever encountered any bandits or outlaws, and said that he himself had spent many days with them in their mountain camps, and that as a rule they were good fellows to be with. The two men parted good friends. Afterwards Dr. Greene learned that his late companion was the leader of a well-known band of robbers.

In 1870 while botanizing on the slope of a snowy range west of Denver in a part of the country not yet settled Dr. Greene started up an inviting valley. After proceeding about a quarter of a mile he saw an Indian on horseback, then another, and another, until there must have been at least 150 Indians in the valley. One, who seemed to be their chief, squared his horse across the path and made signs that he wanted to examine the bag which Dr. Greene carried. When he opened the portfolio and saw nothing but plants he exclaimed, "Ugh! Medicine Man." He then asked Dr. Greene's name, and in return said that his own name was Colorado. This was the name of a notorious chief of the Utes, who was much feared by the whites. Less than three years afterwards this man murdered the entire agency to which the Utes belonged.

In conclusion Dr. Greene again expressed his appreciation of the honor accorded him and of the kind things which had been said regarding the matter of his life's work.

The society also arranged to present Dr. Greene with a book plate as soon as he should approve designs to be submitted by artists.

ASSOCIATION OF TEACHERS OF MATHEMATICS IN THE MIDDLE STATES AND MARYLAND

THE twenty-first meeting of the Association of Teachers of Mathematics in the Middle States and Maryland was held at the State Normal College on November 29, 1913. The following program was given:

10 o'clock

Appointment and reports of committees.

"Are Particular Abilities Necessary for the Pupil to Gain an Understanding of the Elementary and Secondary Mathematics as Usually Given at the Present Time," by Maurice J. Babb and Charles F. Wheelock.

Discussion.

"A Comparison at Equal School Ages of the Attainments in Mathematics of the European and American Schoolboy with a Consideration of Causes and Remedies," by James C. Brown.

Discussion.

2 o'clock

"Mathematics as a Means to Culture and Discipline," by Albert Duncan Yocum.

Discussion.

"The Use of the Question in the Classroom," by Romiett Stevens.

Discussion.

The election of officers resulted as follows:

President: Eugene R. Smith, Park School, Baltimore, Md.

Vice-president: Herbert E. Hawkes, Columbia University, New York City.

Secretary: Howard F. Hart, Montclair High School, Montclair, N. J.

Treasurer: E. D. Fitch, De Lancey School, Philadelphia, Pa.

Council Members: Lao. G. Simons, City Normal College, New York City; W. H. Sherk, La Fayette High School, Buffalo, N. Y.

The next meeting will probably be held at New York City in February.

H. F. HART,
Secretary

PHILOSOPHICAL SOCIETY, UNIVERSITY OF VIRGINIA, MATHEMATICAL AND SCIENTIFIC SECTION

THE second meeting of the session 1913-14 was held November 24. Professor Francis H. Smith presented a paper on "The Foucault Pendulum, and its Possibilities as a Convenient Lecture-room Experiment." A form of apparatus capable of quantitative demonstration within the time of 3 minutes was treated.

L. G. HIXON,
Secretary

SARGENT'S REVOLVING ELECTRIC EXTRACTION APPARATUS

Pat. Dec. 23d, 1913

A most desirable apparatus for any laboratory and especially in Educational Institutions where space is limited and it is desired to demonstrate the action of different solvents simultaneously.

BAUSCH & LOMB UNIVERSAL BALOPTICON (NEW MODEL)

An ideal lantern for general classroom and laboratory work—projects lantern slides, opaque objects and illustrations and transparent objects held horizontally. Some of its features:

1. Simple, durable construction and standardization of parts.
2. Direct lighting of opaque object, covering area 6-in. square and giving brilliant illumination.
3. Correct Position, from left to right, of all images on the screen.
4. Adjustable horizontal object holder.
5. Possibilities of building up for microscopic or moving picture projection.
6. Quick and convenient interchange between all forms of projection.

Price, as illustrated, \$160.00. Special terms to educational institutions. Send for circular.

THE INFLUENCE OF FOURIER'S SERIES UPON THE DEVELOPMENT OF MATHEMATICS¹

IN selecting a subject for to-day's address I have had the difficult task of interesting two distinct classes of men, the astronomer and the mathematician. I have therefore chosen a topic which, I trust, will appeal to both—trigonometric series. Though I propose to treat it only in its mathematical aspects, I shall try to do so in a broad way, tracing its *general* influence upon the trend of mathematical thought.

As you know, the theory of the infinite trigonometric series,

$$(I.) \quad f(x) = \frac{1}{2} a_0 + (a_1 \cos x + b_1 \sin x) \\ + (a_2 \cos 2x + b_2 \sin 2x) + \dots$$

is different *ab initio* from that of the power series,

$$P(x) = c_0 + c_1(x - a) + c_2(x - a)^2 + \dots$$

For the latter the fundamental element is x^n , of which the graph is, for positive x , a monotone increasing function, wholly regular, without peculiarities of any sort. It is therefore in no way surprising that the power series obtained by combining terms of form $c_n x^n$ define the most civilized members of mathematical society—the so-called analytic functions—which are most orderly in their behavior, being continuous throughout their “domains,” possessing derivatives of all orders and a Taylor's series at every point; and so forth. On the other hand, the graph of $\sin nx$ or $\cos nx$ is a wave curve with crests and troughs, whose number in any x interval increases indef-

¹ Address of the vice-president of Section A—Mathematics and Astronomy, American Association for the Advancement of Science, Atlanta, 1913.

nately with n . Accordingly, the functions defined by infinite trigonometric series are obtained by compounding waves of varying intensity and different wave-lengths and may be almost infinitely complicated in their behavior. This fact was fraught with vital consequences for mathematical development.

A further distinction between the trigonometric and power series appears in respect to the values which their argument may take. The convergent power series $P(x)$ has significance for at least a limited domain of imaginary values of x ; on the other hand, it is possible for trigonometric series to define functions which have no meaning except for real values of x . As, therefore, the trigonometric series has a functional content totally different from that of the power series, its influence was felt first, and primarily, in the development of the notion of a function of a real variable.

The concept *function* was at first vague, as vague and indefinite as our geometrical intuitions. It had its root in the 17th century in the analytic geometry of Descartes. Here the variation of y with x along a curve inevitably suggests the notion of a function. The first published definition of the term appeared in 1718 when John Bernoulli defined a function of a variable as "*an expression which is formed in any manner from the variable and constants.*" Thirty years later, in his "Infinitesimal Analysis," Euler defined it in like manner except that the function is now an "*analytic expression.*" What is meant by "analytic expression" is not explained, but from his definition of special classes of functions it would appear that the term denoted an expression put together in terms of the variable and constants by a finite or infinite number of operations of addition, subtraction, multiplication, and division. Differ-

entiation and integration were also undoubtedly permissible.

About this time there began the famous controversy over the mathematical representation of a vibrating string. This satisfies the well-known differential equation

$$\frac{\partial^2 w}{\partial t^2} = a^2 \frac{\partial^2 w}{\partial x^2},$$

where a is a certain constant, x the position of a particle on the string when taut, and w its transverse displacement at time t . A solution of this problem for the case of fixed end points was given by d'Alembert in 1747 under the form

$$w = f(x + at) - f(at - x),$$

where $f(x)$ denotes an arbitrary function whose nature he apprehended too narrowly. But he claimed to have the general solution inasmuch as his solution involved an *arbitrary* function.

This shot into mathematics the question: *What is an arbitrary function?* Even to-day this question is a vexing one, owing to disagreement in the point-set theory concerning certain principles of logic which cluster around the "*Princip der Auswahl*" as a center. But mathematicians had not then arrived at the subtleties of the present day. Their difficulties were really caused more by imperfect notions concerning a function than by the degree of arbitrariness. On the basis of the above definition of a function then current, Euler maintained that d'Alembert's solution was particular, rather than the most general possible. He rightly apprehended the nature of the physical problem and saw that the motion of the string subsequent to the initial instant was completely determined by the initial form of the string and the initial velocities of its points. Now the initial shape of the string could be a continuous geometrical curve composed of successive pieces whose forms are absolutely independent of one

another. To represent these pieces, Euler claimed that an equal number of different analytic expressions, or arbitrary functions, were necessary. Hence, as d'Alembert's solution involved only *one* arbitrary function, it could not be the general solution of the problem.

In these considerations of Euler there is a sharp antithesis between geometry and analysis. In Euler's thought the independent pieces of the above curve formed "*curvæ discontinuæ seu mixtæ seu irregulares.*" There was a blind belief that the definition of a curve in any interval by a mathematical expression carried with it a definite continuation of the curve beyond the interval, the violation of which was a violation of analysis. Thus the question was raised as to the relative power of mathematically constructible expressions and of geometric representation, and it was decided that geometric form transcends analytic expression rather than the converse.

The dual character of this controversy was changed into a triple one by Daniel Bernoulli, who first introduced Fourier's series into physics and obtained the solution of the equation of the vibrating string with fixed end points under the form of a trigonometric series,

$$y = \sum_{n=1}^{\infty} a_n \sin \frac{n\pi x}{l} \cos \frac{n\pi at}{l},$$

where l denotes the length of the string. The separate terms of this series give the tones and overtones of the vibrating string. Inasmuch as this solution is compounded of an infinite number of tones and overtones of all possible intensities, Daniel Bernoulli claimed that he had obtained the general solution of the problem.

For $t=0$ the above equation gives as the initial form of the string,

$$y = \sum_{n=1}^{\infty} a_n \sin \frac{n\pi x}{l}.$$

The question then at once arose whether

d'Alembert's arbitrary function was capable of expansion into such a sine series. To Euler this seemed unthinkable. It was, so to speak, against the laws of the game, it was contrary to the rules of analysis that arbitrary, non-periodic functions could be represented in terms of periodic functions. Hence to Euler, Bernoulli's solution of the problem appeared even more limited than that of d'Alembert.

I have not the time to follow further this controversy, nor to show how d'Alembert and Lagrange united with Euler in declaring Daniel Bernoulli wrong in his claim. Yet not withstanding this overwhelming preponderance of authority Daniel Bernoulli was right. The controversy gradually languished without any clear conclusion till 1807, twenty-five years after Bernoulli's death, when Fourier presented to the French Academy one of the first of his communications which were summed up in 1822 in his "Analytic Theory of Heat." In this communication he startled Lagrange with the absolutely revolutionary doctrine that an arbitrarily given curve or function, irrespective of its nature, could be represented in any interval by a trigonometric series. Fourier sought no strict proof of his assertion, but the concrete examples which he gave vindicated its force. The precise limitations necessary to make the assertion exactly true remained, and to some extent still remain, for his successors to ascertain.

Fourier's result not merely vindicated Daniel Bernoulli's claim for his series, but showed that his claim fell far short of the reality. At a single blow it shattered hopelessly the notion of Euler and his contemporaries that a mathematical function could be carried continuously beyond the interval of definition in only a single way. But Fourier's examples went further than this. The arbitrary curve which he represented

by his series (I) could consist of separate pieces of any sort, not merely having no logical or definitional dependence on one another, but even not connecting successively at their ends. Thus by virtue of Fourier's assertion the power of representation through analytic expression is at least as great as the power of geometric picturization.

When once it was realized that mathematical expression could be adapted to the most diverse and unrelated demands upon it, no logical stopping-point could be seen short of the definition to-day accepted for a function of a real variable, and often referred to as the Dirichlet definition of a function. If, namely, to every value of x in an interval there corresponds a definite value of y (no matter how fixed or determined), y is called a function of x . For example, y may be equal to $+1$ at all rational points which are everywhere dense in any interval, and equal to 0 at the irrational points which are likewise everywhere dense. The Fourier series has thus necessitated a radical reconstruction of the notion of a function. *This is the first of its services which I wish to emphasize, the development and complete clarification of the concept of a function.*

Without loss of generality the interval in which the representation of the function by the series is required may be supposed to lie between $-\pi$ and $+\pi$. The series has then the form (I.) hitherto assumed. To determine its coefficients from the function Fourier used for the most part the equations,

$$a_n = \frac{1}{\pi} \int_{-\pi}^{\pi} f(x) \cos nx dx,$$

$$b_n = \frac{1}{\pi} \int_{-\pi}^{\pi} f(x) \sin nx dx;$$

but this determination, as Fourier himself stated, had been made by Euler before him. Trigonometric series whose coefficients can

be obtained from the function represented in this manner are now called *Fourier's series* in distinction from trigonometric series whose coefficients can not be so obtained through integration. I have, however, in the title of my paper used the term "Fourier's series" in the older and broader sense as synonymous with all series of the form (I.).

The consideration of trigonometric series from a strict mathematical standpoint marks a second epoch in their history. This began with Dirichlet in 1829 in a memoir remarkable for its combination of clearness and rigor. Here he first determined accurately a set of sufficient conditions for the expansion of a function into a Fourier series. These familiar "Dirichlet conditions" it is scarcely necessary to repeat.

The extension of his results was at once sought, in particular by Riemann in a Göttingen Habilitations-Dissertation, which bore the title "Ueber die Darstellbarkeit einer Function durch eine trigonometrische Reihe." Riemann's aim was, however, to determine the *necessary* conditions for the representability of the function by the series. Must the function be integrable, as required in the sufficient conditions of Dirichlet? Must it have only a finite number of maxima and minima and of discontinuities? Such questions as these were easily answered by him in the negative, and a flood of light was poured upon the problem of representability but without making visible its complete solution. Possibly it was for this reason that this Habilitationsschrift, though delivered in 1854, was not published until thirteen years later, and then only after Riemann's death. Yet the work is a classic. As has been said of the poet Coleridge, so it could be said of Riemann, he wrote but little, but that little should be bound in gold.

To put the theory of Fourier's series on

a broader basis, Riemann perceived that first of all it was necessary to sharpen and widen the concept of an integral. Initially Leibnitz had thought of integration as a summation process, but this notion was forced into the background by its definition as the reverse of differentiation, until revived by Cauchy in 1823. He then defined the integral of a *continuous* function as most of us were taught to define it. The interval of integration was divided into n parts δ_i , each δ_i was multiplied by the value of the function $f(x_i)$ at its beginning, and the integral was defined as the limit of the sum $\sum \delta_i f(x_i)$ when the number of parts increased indefinitely, their size diminishing indefinitely. Because of the continuity of the function this definition of the definite integral was equivalent to that framed by means of the reverse process of differentiation. Riemann dismisses altogether the requirement of continuity for the function, and in forming the sum multiplies each subinterval δ_i by the value of the function, not necessarily at the beginning of the interval, but at a point ξ_i *arbitrarily* assumed in the subinterval. If, then, a limit exists for the sum $\sum \delta_i f(\xi_i)$, irrespective of the manner of partitioning the interval and of the choice of the points ξ_i , this is called the integral. Thus he redefined the fundamental concept of the integral calculus, making it entirely independent of the differential calculus. This definition, often referred to as the Riemann definition of an integral, has now become the universally accepted one and is the basis of scientific treatment of the integral calculus. *Thus a second service of Fourier's series has been in laying the foundation of the modern integral calculus, and in such wise that it bid fair to completely eclipse the differential calculus in importance and reach.*

Riemann's memoir may also be characterized as the beginning of a theory of the

mathematically discontinuous. The work of Fourier had disclosed that mathematical expressions could portray functions with breaks, and the exacter but more limited investigation of Dirichlet drew still further attention to discontinuities. Riemann's definition of an integral did more; with one leap it planted the discontinuous function firmly upon the mathematical arena. In his integrable functions was comprised a class of functions whose discontinuities were infinitely dense in every interval, no matter how small—though indeed, as we now know, they are not totally discontinuous. One example which he gave was the integrable function defined by the convergent series,

$$1 + \frac{(x)}{1^2} + \frac{(2x)}{2^2} + \frac{(3x)}{3^2} + \dots,$$

in which (nx) denotes the positive or negative difference between nx and the nearest integral value, unless nx falls half way between two consecutive integers, when the value of (nx) is to be set equal to 0. The sum of the series was shown to be discontinuous for every rational value of x of the form $p/2n$, where p is an odd integer relatively prime to n .

This example and others, such as that of an integrable function with an infinite number of maxima and minima which was incapable of representation by a Fourier's series, were exceedingly stimulating. The investigation so impressed the imagination of Hermann Hankel as to call forth his notable memoir "Über die unendlich oft oszillierenden und unstetigen Functionen" in which he unfolds his principle of "condensation of singularities," a memoir so important that it has even been said to "entitle him to be called the founder of the independent theory of functions of a real variable." It would appear to me that this distinction could be assigned with equal propriety to Riemann, for historically the

first of the two or three principal sources of this theory is to be found in Riemann's application of integration to discontinuous functions in his memoir on "the representability of a function by Fourier's series."

The above example of Riemann is notable for giving a mathematical expression for a discontinuous function incapable of graphical representation. I have already pointed out how Euler conceived of graphs so arbitrary as to be impossible of representation through an "analytic expression." The scales were now turned decisively to the other side, though it was not till later that it was recognized that our geometric figures have only an approximating character which our mathematical equations refine.

But the full power of mathematical expression was not realized until 1872-1875, when Weierstrass startled the mathematical world with an example (first published by Du Bois Reymond in 1875) of a continuous function having nowhere a derivative, or, in other terms, of a continuous curve without a tangent. The function given by Weierstrass was a trigonometric series

$$\sum_{n=1}^{\infty} b^n \cos a^n \pi x,$$

in which b is a positive constant less than 1 and a a fixed odd integer large enough to make ab exceed a certain value. Weierstrass states also that Riemann is supposed to have shown that the series

$$\sum \frac{\sin n^2 x}{n^2}$$

represented a function of like property, but the proof was not known. The failure of the continuous function of Weierstrass to be differentiable is due to the possession of an infinite number of maxima and minima in any interval, however small.

This example completed the separation between differentiable and continuous func-

tions. It shows that *the former are only a subclass of the latter*, a result not even surmised by the boldest geometrical intuition. *This is the third influence of Fourier's series which I wish to emphasize.* So far as I know, this is the only one of its results which vitally affects geometric theory. It reveals the transcendence of analysis over geometrical perception. It signalizes the flight of human intellect beyond the bounds of the senses.

I return now to trace further the march of the function theory of the real variable. The second principal element in its formation seems to me to have been the concept of *uniform convergence*. This also seems to have been suggested chiefly by study of trigonometric series. Originally it was supposed that the sum of a convergent series of continuous functions shared the common properties of its terms and accordingly was continuous. Even so great a mathematician as Cauchy fell for a time into this error. The fallaciousness of this assumption was first pointed out by Abel in 1826 in his well-known memoir on the binomial series. Here he also discusses the series

$$f(\phi) = \sin \phi - \frac{\sin 2\phi}{2} + \frac{\sin 3\phi}{3} - \dots, \quad (2)$$

every term of which is continuous. Clearly the sum vanishes whenever ϕ is a multiple of π . If ϕ lies between $m\pi$ and $(m+1)\pi$, the sum is $\phi/2 - \nu\pi$, where ν denotes the

FIG. 1.

half of m or $m+1$, according as m is even or odd. Consequently, when ϕ passes through an odd multiple of π , the sum has a discontinuity of amount π , as is indicated in the adjoining graph. This re-

sult is in sharp contrast with the continuity of the sum which he demonstrates for the binomial and other real power series. At the same time he establishes the circular form of the region of convergence of the binomial series. Here, then, appears the initial cleavage between the theories of real and of analytic functions.

The difference between the trigonometric and the power series in respect to continuity is naturally to be sought in the character of the convergence at the points of continuity and of discontinuity. This difference was pointed out by Stokes in 1847 and by Seidel a year later. Both discovered the infinitely increasing slowness of convergence of the series on approaching a discontinuity of its sum. Consequently a discontinuity can not be enclosed in any interval, however small, in which the convergence is throughout "von gleichem Grade." In more modern parlance, the convergence is non-uniform. Seidel in his introduction explicitly points out that the erroneous conclusion of Cauchy's conclusion (see above) is obvious from the existence of discontinuities in functions represented by Fourier's series, and he is evidently incited thereby to seek a cause for the discontinuity. The origin of Stokes's study is sufficiently obvious from its title: "On the Critical Values of the Sum of Periodic Series." His failure to appreciate the importance of his own convergence discussion is evident from the fact that it is not even mentioned in the opening analysis of his lengthy memoir.

A third discoverer of uniform convergence was Weierstrass, who is known to have been in possession of the notion as early as 1841. Through his followers (Heine and others) it gradually percolated into the mathematical literature. Unlike Seidel and Stokes, he thoroughly realized its importance. As Osgood has well said in his *Functionentheorie*, he developed uniform

convergence into one of the most important organs "(methods) of modern analysis." The origin of the notion in the case of Weierstrass I have been unable to ascertain. A conjecture or surmise may therefore be pardoned. As is well known, the work of Weierstrass is rooted in that of Abel, the central theme or core being the theory of Abelian functions. It would not seem to be altogether improbable that both Weierstrass's theory of the analytic function and his concept of uniform convergence had as their starting point Abel's memoir on the binomial series. For here, on the one hand, with the demonstration of the circular form of the region of convergence of the binomial series, we find a proof of the continuity of the series which involves implicitly the idea of uniform convergence; on the other hand, we have in the footnote a series with discontinuities due, in fact, to non-uniform convergence. It would be a small matter for the discriminating Weierstrass to see that the continuity of the sum could not be carried over from the binomial to the trigonometric series, because there was not the same kind of convergence in the latter case. If this surmise is correct, the discovery of uniform convergence in the case of the third discoverer also is closely connected with a Fourier series.

I have dwelt at some length on uniform convergence because its discovery marks both the culmination of the first and older epoch in the treatment of functional series, and the beginning of a new one. In uniform convergence and a study of the discontinuous we have sought for the chief springs of the modern *theory of functions of a real variable*. By so doing we are led to assign as a fourth great service of Fourier's series the genesis of this theory. It is not to be forgotten, however, that other sources have also copiously contributed. The morphology of one member of a body

must be in many ways perverted, if studied without correlation to the other members. But, after all, it is the Fourier series which gave the initial push and chief impetus to the construction of the function theory of the real variable.

This becomes still plainer if we take into consideration the comparatively recent point-set theory. Originally an off-shoot of the real function theory and still often treated by itself, it has been largely absorbed back into this theory, and its concepts already permeate analysis. Its founder was George Cantor, who was trained in the exact yet fertile school of Weierstrass. His earliest papers presaging this theory relate to a trigonometric series.

Two problems occupy his attention. The first is to show that if the series $\sum (a_n \sin nx + b_n \cos nx)$ is convergent throughout an entire interval, except possibly for a finite number of points, the coefficients a_n and b_n have for $n = \infty$ the limit 0. The second is to establish the uniqueness of the development of a function into a trigonometric series; in other words, to prove that when $\sum (a_n \sin nx + b_n \cos nx)$ is identically 0 over an interval, then each and every a_n and b_n must be 0. The requirement of convergence of the sum in the one case and of its vanishing in the other, was originally made for the entire interval, but Cantor found that it could be remitted for certain infinite aggregates of points without affecting the truth of the conclusions. He was led consequently to introduce the notion of the "*derivative of a point-set*." Consider with him the set of points for which the requirement is omitted, and suppose that they cluster in infinite number in the vicinity of any point. This will be called a limit-point of the set. The totality of these limit-points is called the first derived set, or first derivative. This derived set of points may also have cluster points which

form the second derivative; and so on. After introducing this concept, Cantor proved that the requirement could be remitted for any set of points whose n th derivative contains only a finite number of points and whose $(n+1)$ th derivative accordingly vanishes.

In these very early papers of Cantor we have very clearly the beginning of his point-set theory. His attention is here concentrated upon an infinite aggregate of points, and the notion of the derived point-set was the first of the concepts by means of which he is able to distinguish between different infinite aggregates of points. Prior to Cantor no effort was made to distinguish qualitatively between them. To be sure, mathematicians were thoroughly conversant with the distinction between a continuous curve or set of points, on the one hand, and a merely dense aggregate of points such as the totality of points with rational coordinates. The raw material lay at hand for a beginning, especially in the work of Riemann and others on integration. Cantor alone saw the imperativeness of the need. In comparing infinite sets of objects and seeking a theory of the truly infinite he blazed a new path for the human mind. *As a fifth and a mighty influence of Fourier's series we have, therefore, to record the historic origin of the theory of infinite aggregates.*

Thus far in my sketch I have traced one strong, single current of influence of the Fourier's series. I have now to indicate some other effects without close relation to the foregoing.

In Fourier's "Analytical Theory of Heat" there are found what are said to be the first instances of the solution of an infinite number of linear equations with an infinite number of unknowns. He has, for example, to determine the coefficients in the equation:

$$1 = a \cos y + b \cos 3y + c \cos 5y + \dots$$

For this purpose he differentiates an even number of times, obtaining thus the system of equations

$$0 = a \cos y + b 3^n \cos 3y + c 5^n \cos 5y + \dots \quad (n=2, 4, \dots)$$

Combining this with the preceding equation and putting $y=0$, he obtains an infinite number of equations of first degree with an infinite number of unknowns, a, b, c, \dots . To solve these he uses the first m equations to determine the first m unknowns, suppressing all the other unknowns, and finally determines their limiting values as m increases indefinitely. There is no time to point out the lack of rigor. Fourier uses his mathematics with the delightful freedom and naïveté of the physicist or astronomer who trusts in a mathematical providence.

This suggestive line of attack was not followed up, and indeed could not be, prior to the development of a theory of infinite determinants. When such a system of linear equations with an infinite number of unknowns came again to the foreground, the inciting cause was again a trigonometric series. I refer, as you know, to the work of our own astronomer, Hill. In his memoir on the "Motion of the Lunar Perigee" he had before him a differential equation of the following form, with numerical coefficients:

$$\frac{d^2 w}{dt^2} = 2w \left(2 + \theta_1 \cos 2\tau + \theta_2 \cos 4\tau + \dots \right).$$

Assuming a solution in the form

$$w = e^{ic\tau} \sum_{n=-\infty}^{n=+\infty} b_n e^{2in\tau}$$

(which except for the factor $e^{ic\tau}$ is only a trigonometric series under another guise), Hill obtains for the determination of c and the b_n an infinite system of equations linear in the b_n . The elimination of the b_n then gives c as the root of a certain infinite

determinant, and then the values of the b_n are also found by use of infinite determinants.

The importance of Hill's results at once attracted the genius of Poincaré whose attention had, in fact, been previously drawn by Appell to an infinite system of linear equations. Poincaré now proceeded to consider the question of the convergence of infinite determinants, and in so doing laid a sound foundation for a new mathematical subject. In this new theory of infinite determinants the central thought is the passage, under restrictions to be properly ascertained, from a finite to an infinite system of linear equations. This principle here employed has been since applied in an even more striking manner by Fredholm, who was led through its use to his historic solution of a class of integral equations. In the theory of these equations the infinite determinant plays an indispensable rôle. *A sixth influence of Fourier's series is thus seen in the origin of a theory of infinite determinants*, also indirectly in the theory of integral equations for which it has supplied an important tool.

The seventh and the last influence on which I shall specifically dwell is more subtle, not so easily pointed out or demonstrated as some of the foregoing, but nevertheless one of the most far-reaching and probably the most pervasive of all. The physicist, astronomer, or mathematician has again and again to expand an arbitrary or assigned function into a series of functions, the nature of which varies with the problem before one. When once the idea and method of expressing an arbitrary function in series of sines and cosines have been won, they can be extended to other series of functions, as for instance series of Bessel's functions, zonal harmonics, Lamé polynomials, spherical harmonics. For such developments the trigonometric series with its

applications has repeatedly served as a guide post. Numberless analogous results have been suggested thereby, though without definite statement of the fact. To take an example at random, the relation

$$\int_0^1 P_{2n}(x)P_{2m}(x)dx = 0 \quad (m \neq n)$$

has its trigonometric analogues

$$\int_0^\pi \cos n\theta \cos m\theta d\theta = 0.$$

Who can deny, or who can affirm, in many such individual instances that the suggestion came from the trigonometric series? Yet in the bulk the debt is so great that he who runs can read it.

It is especially in connection with boundary value problems that we encounter series of functions. Now the trigonometric series was the inevitable tool for the first boundary value problems—those of vibrating strings, rods, columns of air, etc. Later, when Fourier crystallized the boundary value problems into classic shape, he used trigonometric series and, to lesser degree, similar series of Bessel's functions, obviously because these afforded him the simplest tools for the simplest problems. From series of sines of multiple angles he was led by certain problems in heat conduction to series of form $\sum c_i \sin a_i x$, where the a_i are roots of a certain transcendental equation. Thence the orientizing influence of Fourier's series is continued down to the modern development of normal functions in the theory of integral equations. All such influences are in the very warp and woof of mathematical development and can not be disentangled. To minimize or ignore them would be to give a distorted picture. They form a most vital and leading part of the mighty theory of harmonic and normal functions and of the boundary value theory.

The extent of these influences in the past gives rise naturally to the question of

whether the trigonometric series will continue to exert such a moulding influence in the future. Certain results of Baire to be shortly mentioned incline one to answer negatively. Yet the questions regarding the convergence of the series and the character of the functions which it can represent are even to-day incompletely answered. When new implements are invented, it is still to these unanswered questions that the investigator naturally turns to test their worth, as, for example, Lebesgue with his great new concept of an integral which has application when Riemann's integral is void of sense, or Fejér with a method of summing a divergent series. Also the Fourier series still offers an occasional surprise. Who indeed would have anticipated Gibbs's discovery, since extended by Bôcher, which relates to the approximation curve $y=S_n(x)$, obtained by equating y to the sum of the first n terms of the series (2) above? As n increases indefinitely, the amount of the oscillation of the curve in the vicinity of each point of discontinuity of the limit does not tend toward the measure of the discontinuity, as would be supposed, but to this value increased in a certain definite ratio! But it may be reasonably expected that these surprises will become fewer and less important.

In this brief review I have neglected certain less analytic aspects, such as trigonometric interpolation and the use of the series in computation and in the perturbation theory. It has also not been necessary to emphasize the simplicity of structure of the series and its adaptation to computation. Neither do I need to speak of its correspondence in structure to so many periodic phenomena of nature, sound, light, the tides, etc. But I do wish, in closing, to emphasize and examine further, one aspect implied in all my preceding con-

siderations, the wonderful *pliability* of the series.

It was this pliability which was embodied in Fourier's intuition, commonly but falsely called a theorem, according to which the trigonometric series (I.) "*can express any function whatever between definite values of the variable.*" This familiar statement of Fourier's "theorem," taken from Thompson and Tait's "Natural Philosophy," is much too broad a one, but even with the limitations which must to-day be imposed upon the conclusion, its importance can still be most fittingly described as follows in their own words: The theorem "*is not only one of the most beautiful results of modern analysis, but may be said to furnish an indispensable instrument in the treatment of nearly recondite question in modern physics. To mention only sonorous vibrations, the propagation of electric signals along a telegraph wire, and the conduction of heat by the earth's crust, as subjects in their generality intractable without it, is to give but a feeble idea of its importance.*"

Truly, the theorem is so comprehensive in its mathematical content that we mathematicians may well query with one of my colleagues whether it may not have conditioned the form of physical thought itself—whether it has not actually forced the physicist often to think of complicated physical phenomena as made up of oscillatory or harmonic components, when they are not inherently so composed.

It is this same pliability of the series that has been a source of perpetual delight and surprise to the mathematician. It has revealed an undreamt-of power in analysis. It has stimulated intuition and vigor, and has helped to usher in a modern critical era in mathematics similar in spirit to the Greek period. It has separated differentiable from continuous functions; it has

put the integral calculus on a basis of independence of the differential calculus; it has focused attention upon sets of irregularities and discontinuities whose study has started the point-set theory; it has opened the field of discontinuous functions to analysis and, above all, has engendered a theory of functions of the real variable.

To the mathematician the theory of analytic functions for some time appeared to be of much greater importance than the freaky theory of the real variable, because almost all the important functions of mathematics are analytic. Also, the same has been hastily assumed for physics because the real and imaginary components of an analytic function are harmonic functions satisfying Laplace's equation. But this is to ignore features of at least equal, if not of superior, importance. Not long ago many thought that the mathematical world was created out of analytic functions. It was the Fourier series which disclosed a *terra incognita* in a second hemisphere.

Here, in the new hemisphere, the mathematician has advanced beyond the boundary of the trigonometric series. It has been found that discontinuous functions representable through such series form a thoroughly restricted class. They belong to what Baire calls the first class of functions which are limits of convergent sequences or series of continuous functions, themselves of "class 0." These in turn may be used to generate new functions. Even as non-uniformly convergent Fourier series may give rise to discontinuous functions of Class 1, so non-uniformly convergent series of functions of this class may give a new sort of functions of Class 2, and so on. Indeed, to every transfinite number α of the first or second class there corresponds, as Lebesgue has shown, a definite class of functions. *Thus the Fourier series has, after all, a very limited range of representation*

in the totality of functions mathematically conceivable.

Even for functions of Class 0 or 1 the trigonometric series has a limited power of representation. This is manifest from an example given by Paul Du Bois Reymond of a continuous function which can not be represented by a trigonometric series. It remains to determine in the future just what properties are necessary and sufficient to characterize those functions of Classes 0 and 1 which are expressible by means of trigonometric series.

Earlier in my paper I pointed out that the generality of functions representable through Fourier's series was so great that the mathematician was led irresistibly to the Dirichlet definition of a function. If, namely, to every value of x in an interval we have a corresponding value of y , then y is called a function of x , no matter how the correspondence is set up, whether by a graph, a mathematical expression, a law, or any other way. To-day the pendulum has swung back to the old question of Euler. The study of representability in terms of trigonometric series has been succeeded by the broader question of the possibility of analytic expression in general. Now every continuous function, as is well known, can be represented by a uniformly convergent set of polynomials. Starting then from the totality of polynomials as a basis of functions for Class 0, we arrive successively at Baire's and Lebesgue's classes of functions corresponding to or, if you prefer, marked, by the transfinite numbers of the first and second classes.

Do these different classes of functions comprise all which are "*analytically expressible*"? Before answering the question it is necessary first to sharply define the phrase "*analytically expressible*." This is done by Lebesgue. Then, after broadening the content of these classes in a manner

I have not the time to describe, he goes on to show that they do in truth comprise all such functions. The final question then confronts us: Are all possible functions included which are defined in accordance with the general definition of Dirichlet? In other words, are there functions *incapable of being "analytically expressed"*? Lebesgue by an example shows that this is the case. Our study of the Fourier series opened with the question: What is an arbitrary function? Here, at last, apparently, we have discovered the existence of a function of such a height or depth of arbitrariness as to be mathematically inexpressible. Having started with the Fourier series on a voyage of exploration, shall we conclude by saying that there is for us an unattainable pole?

EDWARD B. VAN VLECK

UNIVERSITY OF WISCONSIN

UNIVERSITY REGISTRATION STATISTICS

THE registration returns for November 1, 1913, of thirty of the leading universities of the country will be found tabulated on the following page. Specific attention should be called once again to the fact that these universities are neither the thirty largest universities in the country, nor necessarily the leading institutions. The only universities which show a decrease in the grand total attendance (including the summer sessions) are Harvard, Western Reserve and Yale, the attendance of the two institutions last named having remained practically stationary. The largest gains in terms of student units, including the summer attendance, but making due allowance by deduction for the summer session students who returned for instruction in the fall, were registered by New York University (965), Illinois (944); Columbia (927), Wisconsin (749), Pennsylvania (681), California (614), Iowa (598),

Ohio State (503), Chicago (483), and Michigan (388). Last year there were only five institutions that showed a gain of over 300 students, namely, Columbia, California, New York University, Texas and Harvard. Omitting the summer session attendance, the largest gains this year have been made by Illinois (887), New York University (772), California (640), Pennsylvania (571), Iowa (538), Wisconsin (493), Ohio State (434), Michigan (381), Chicago (353), Syracuse (305), Washington University (267), and Columbia (255). It will thus be seen that this year twelve institutions exhibited an increase of over 200 students in the fall attendance, as against eight in 1912 and four in 1911. Of these institutions eight are in the west and four in the east.

According to the figures for 1913, the thirty institutions, inclusive of the summer session rank as follows: Columbia (9,929), California (7,071), Chicago (6,834), Michigan (6,008), Pennsylvania (5,968), Wisconsin (5,890), Harvard (5,627), Cornell (5,612), New York University (5,508), Illinois (5,259), Ohio State (4,111), Minnesota (3,932), Northwestern (3,877), Syracuse (3,845), Yale (3,263), Missouri (3,135), Texas (3,106), Nebraska (2,850), Kansas (2,610), Iowa (2,542), Tulane (2,298), Indiana (2,271), Pittsburgh (1,906), Cincinnati (1,871), Stanford (1,756), Princeton (1,599), Western Reserve (1,370), Johns Hopkins (1,311), Washington University (1,225), and Virginia (885), whereas last year the order was Columbia, California, Chicago, Harvard, Michigan, Cornell, Wisconsin, Minnesota, Pennsylvania, New York University, Illinois, Northwestern, Ohio State, Syracuse, Yale, Texas, Missouri, Nebraska, Kansas, Tulane, Iowa, Cincinnati, Pittsburgh, Stanford, Princeton, Western Reserve, Washington University, Johns Hop-

kins, Virginia. If the summer-session enrollment be omitted, the universities in the table rank in size as follows: Columbia (6,403), Pennsylvania (5,305), Michigan (5,304), California (5,225), Harvard (4,922), Illinois (4,835) and New York University (4,835), Cornell (4,760), Wisconsin (4,450), Northwestern (3,776), Chicago (3,719), Ohio State (3,708), Syracuse (3,699), Minnesota (3,616), Yale (3,263), Missouri (2,547), Nebraska (2,482), Texas (2,373), Kansas (2,308), Iowa (2,294), Pittsburgh (1,906), Cincinnati (1,871), Stanford (1,743), Princeton (1,599), Indiana (1,417), Western Reserve (1,370), Tulane (1,244), Washington University (1,225), Johns Hopkins (1,012) and Virginia (885), whereas last year the order was: Columbia, Michigan, Harvard, Cornell, California, Pennsylvania, New York University, Wisconsin, Illinois, Northwestern, Minnesota, Syracuse, Chicago, Ohio State, Yale, Nebraska, Missouri, Texas, Kansas, Cincinnati, Pittsburgh, Iowa, Stanford, Princeton, Western Reserve, Tulane, Washington University, Virginia, and Johns Hopkins.

Including the summer-session attendance the largest gains in the decade from 1903 to 1913 were made by Columbia (5,372), California (3,594), New York University (3,331), Pennsylvania (3,324), Chicago (2,688), Wisconsin (2,669), Ohio State (2,423), Cornell (2,174), Michigan (2,082) and Illinois (2,020).

So far as the individual faculties of the various universities are concerned, Harvard with 2,350 men and 564 women (Radcliffe College) leads in the number of college undergraduates, being followed by California, with 1,112 men and 1,626 women; Michigan, with 1,736 men and 784 women; Stanford, with 1,243 men and 500 women; Chicago, with 936 men and 767 women; Kansas, with 942 men and 688

Note.—The grand totals of the University of Minnesota prior to 1912 are inclusive of "extension and similar students," which were listed separately in 1912 and 1913, hence the apparent decrease.

* Includes schools of mines, engineering, chemistry and related subjects.

† Included elsewhere.

‡ 1,220 students in attendance on summer courses.

women; Wisconsin, with 828 men and 776 women; Minnesota, with 639 men and 882 women; Texas, with 811 men and 709 women; Columbia, with 841 men and 623 women; Yale, with 1,402 men; Nebraska, with 541 men and 733 women, and Princeton, with 1,267 men.

In agriculture, Cornell leads with 1,354 students, being followed by Wisconsin with 968, Ohio State with 889, and Illinois with 792. In architecture Illinois with 351 is followed by Pennsylvania with 259, and Columbia and Cornell with 143 each. Washington University, with 305 art students, leads in that field, being followed by Syracuse with 178; while New York University continues to lead in commerce with 2,013 students, being followed by Pennsylvania with 1,430, Northwestern with 567, Wisconsin with 374, Illinois with 282, and California with 280. The largest dental school is at Pennsylvania, where 589 students are enrolled, as compared with 566 at Northwestern, 282 at Michigan, and 268 at Minnesota. Northwestern has the largest divinity school, enrolling 233 students, as against 125 at Chicago, 100 at Yale and 56 at Harvard; these are the only universities in the list that maintain schools of theology.

Syracuse has 220 students of forestry, Ohio State 65, Minnesota 41, Nebraska 36, and Yale 32; at California, Illinois, Michigan and Missouri, the forestry students are counted in with other departments. Columbia has a long lead in the number of non-professional graduate students, there being no less than 1,496 students enrolled in its faculties of political science, philosophy and pure science. Columbia is followed by Harvard with 489 students, Chicago with 480, Pennsylvania with 438, and California with 408. Columbia has the largest school of journalism, enrolling 106 students as compared with Wisconsin's 91,

Indiana's 73, and Missouri's 64. The largest law school is at New York University, where 771 students are registered in this subject; Harvard follows with 695 students, Michigan with 553, and Columbia with 450. In medicine Illinois leads with 445, being followed by New York University with 432, Tulane with 399, Johns Hopkins with 368, Michigan with 353, Columbia with 341, and Harvard with 306. Syracuse has the largest number of music students, namely, 925, there being 407 at Northwestern and 130 at Kansas. The Teachers College of Columbia University is by far the largest school of education connected with any of the institutions in the list. It has an enrollment this fall of no less than 1670 students, as against 699 at Pennsylvania, 443 at Texas, 421 at Pittsburgh and 420 at New York University. Columbia also has by far the largest school of pharmacy, enrolling 441 students, as against 255 at Illinois, 209 at Pittsburgh, and 135 at Northwestern. As for the scientific schools, Cornell continues to maintain its lead in this branch, enrolling 1,343 students, as against Michigan's 1,282, Yale's 1,133, Illinois's 1,001, California's 828, Ohio State's 811, Wisconsin's 775, Columbia's 665, Pennsylvania's 657, and Minnesota's 638. In veterinary medicine Ohio State leads with 163, being followed by Pennsylvania with 125, and Cornell with 122. All of the above figures for individual faculties are exclusive of the summer-session attendance. The largest summer session in 1913 was at Columbia University, where 4,539 students were enrolled, as against 3,771 at Chicago, 2,363 at California, 2,120 at Wisconsin, 1,408 at Michigan, 1,392 at Cornell, 1,163 at Tulane, and 1,084 at Indiana.

The largest number of officers is found at Columbia, where the staff of teaching and administrative officers consists of 907 mem-

bers, as against 737 at Illinois, 731 at Harvard, 725 at Cornell, and 633 at Wisconsin.

The 638 students enrolled at the University of California in extension and similar courses are distributed as follows: San Francisco Institute of Art 201, Wilmerding School of Industrial Arts 155, University Farm School 187, and short courses in agriculture 95.

The 3,182 students listed under extension and similar courses at the University of Chicago are enrolled in correspondence study courses. The 808 students mentioned under other courses are enrolled in regular university courses given primarily for teachers which meet on Saturday mornings and late in the afternoons.

Among the 84 students of medicine enrolled at the University of Cincinnati, 23 are registered in clinics and pathological work. The 486 students mentioned under other courses are enrolled in evening academic courses.

Of the 3,644 students enrolled under extension and similar courses at Columbia University, 1,152 are students in special classes at Teachers College and 2,492 are students in extension courses.

Of the 1,120 students registered at Cornell University under arts and sciences, 950 are candidates for the degree of A.B. and 170 for the degree of B.Chem. Of the total number of 4,760 students enrolled in the fall, 4,273 are men and 487 women. The students mentioned under extension and similar courses were enrolled in the short winter course in agriculture for 1912-13.

The 113 students mentioned under commerce at Harvard University are enrolled in the graduate school of business administration. Of the 61 students in architecture, 23 are enrolled in landscape architecture, while the 76 students mentioned under scientific schools are enrolled in the graduate school of applied science. Only

one department, forestry, which is a part of the graduate school of applied science, shows a marked decrease, the enrollment having dropped from 18 to 9. This may possibly be accounted for by the fact that this year for the first time students were expected to register in July, instead of in September, and this may not have been sufficiently widely known. Also, the course has been changed somewhat, including general work in the first year and special work in the second year. In landscape architecture, which is also in the graduate school of applied science, there has been a marked increase, 23 students being enrolled this year, as opposed to 15 in 1912, and 7 in 1911.

Of the 350 students given under other courses at the University of Illinois, 310 are enrolled in household science and 40 in library economy. In Chicago, the departments of medicine and dentistry have been reopened with higher entrance requirements—hence the material loss in the registration in these schools as compared with the registration of two years ago.

The students mentioned under scientific schools at Indiana University are pursuing courses in chemistry, provision for technical work being made at Purdue University.

The 86 students given under other courses at the State University of Iowa are enrolled in courses for nurses.

At Johns Hopkins, 169 men and 39 women are enrolled in the graduate school, and 15 are taking graduate work in engineering. Of the 368 students given under medicine, 8 are physicians attending special courses.

Of the 353 students given under medicine at the University of Michigan, 75 are enrolled in the homeopathic medical college.

At the University of Minnesota, agricul-

ture, inclusive of the home economic division, shows a steady growth. The apparent increase in the graduate school is explained by regulations concerning registration rather than by an influx of advanced students. However, impetus has been given to this department by the appointment of Professor Guy S. Ford, formerly of the University of Illinois, as dean. The law school is feeling the full effect of the requirement of two years of academic work for admission to regular courses, also the effect of discontinuing night classes. Many of the subjects heretofore offered by the law school in evening courses have been transferred to the extension department. Heretofore little emphasis has been given to music. This year marks the beginning of a regular four years' course in arts and music leading to the degree of bachelor of arts in music, consequently these students are listed separately this year for the first time. The requirements for admission are the same as for the college of science, literature and the arts. The college of engineering has secured F. E. Mann, of the University of Illinois, to take charge of the department of architecture, and the courses in architecture and architectural engineering have now been permanently established. The requirements for admission are the same as the engineering courses and the B.S. and appropriate professional degrees are granted at the close of four and five years, respectively. The reorganization of the extension division and the advent of Professor R. R. Price, formerly of Kansas University, as director of this department, explain the increased enrollment in this division.

The decrease in enrollment in the school of law at the University of Missouri is due to the fact that during this session all of the three classes in that school are based upon an admission requirement of two

years of college work, while the third-year class of last year was admitted under the former requirement of four years of high school work. There is a decrease in the school of engineering due to a similar reason, but as there has been an increase in the school of mines, the total enrollment in technical schools shows a slight increase. It has been anticipated that a similar decrease would be manifested in the school of journalism. Notwithstanding the fact, however, that there is during the present session only one of the classes which entered under the former requirements as compared with two such classes during the session of 1912-13, the total enrollment in the school shows an increase.

At the University of Nebraska, there is but little change in registration this year as against 1912, the most apparent increase being in the school of agriculture, at the expense of the professional schools.

Every school in New York University with the exception of the veterinary college shows a marked increase. The increase in the college of arts and pure science is due largely to the transfer of the medical preparatory class from the collegiate division to the freshman class of the college.

Of the 296 students enrolled in other courses at Northwestern University, 172 are registered in the school of oratory and 124 are taking courses for nurses. There have been noteworthy increases in attendance in several of the schools of the university, especially in the college of engineering, the dental school, and the school of commerce. There is an increase in the college of liberal arts in spite of the increased tuition fees. The same increase in fees was put into effect in the college of engineering, but, nevertheless, the enrollment is the most encouraging in the history of the college, it being due to a consistent and dignified sys-

tem of publicity. In the dental school, the university is increasingly strict in administering entrance requirements, and yet the enrollment has increased at a phenomenal rate. The increase in the school of commerce is an evidence of the need of such work in a large city; these courses are given in the evening, and the registration is in great part made up of men who are in business during the day. In the statistics of November 1, 1912, the report showed 368 students enrolled in the law school; the figure should be 268.

The 280 students given by Ohio State University under other courses are enrolled in home economics. The 227 students in extension and similar courses represent the enrollment of 1912-13. The fall enrollment shows substantial increases in all colleges except the college of law, which is 13 short of the enrollment November 1, 1912. The largest gains in the colleges have been as follows: agriculture 188, engineering 109, arts 94, and education 37. The increase in the fall enrollment is 434. These increases are probably due to a revival of interest among the alumni of the university. Two years ago, under the able leadership of Mr. Ralph D. Merston, of New York, the alumni and former students of the university were reorganized into a live association. Local organizations have been formed in all parts of the state and in all prominent cities of the country. A permanent secretary, who gives all of his time to alumni interests, has been employed. The annual observance of "Ohio State Day" by alumni and former students throughout the state and country has done much to bring the university into prominence in local communities. A new department of competitive and recreative athletics was created by the board of trustees last June. The director of athletics and the men associated with him have been

given faculty rank. A limited amount of credit will be given for work in courses in the teaching of athletics. A new course in applied entomology, leading to the degree of bachelor of science in entomology, has been added to the curriculum. Two new combination courses have also been arranged, arts—agriculture and arts—home economics, making it possible for a student to receive two degrees in five years. The last General Assembly of Ohio authorized the establishment of an engineering experiment station at the university and the organization of a college of medicine. No definite action has been taken by the board of trustees. The General Assembly also authorized and directed the university to establish and organize a university extension division, for the purpose of carrying on educational extension and correspondence instruction throughout the state.

At the University of Pennsylvania, the 379 students listed under extension and similar courses are enrolled in courses at Wilkes Barre (185) and Scranton (194). The 9 students listed under other courses are enrolled in hygiene. The 699 students listed under pedagogy are enrolled in college courses for teachers. Nearly all departments share in the gains in enrollment, the most noticeable increase being in the Wharton school of finance and commerce, and in the evening school of accounts and finance. The school of architecture continues its advance in registration, the total this year being 259, or an increase of 43. The graduate school, with a total enrollment of 438, is 67 ahead of the preceding year. The law school, with a total enrollment of 381, is just 2 short of the figures of last year. The medical school is still feeling the effects of the raise in entrance requirements put into effect within the past few years. The enrollment of 283 shows a loss of 37. The dental school, with 589

students, has an increase of 80. Other departments show slight gains or losses which are negligible.

At the University of Pittsburgh, the 157 students listed under other courses are male candidates for degrees in economics. Of the 411 students given under extension and similar courses, 127 are taking teachers' courses without credit and 284 are enrolled in the evening school.

The students at Leland Stanford University listed under law and medicine and the graduate school are all included also under the college.

At Syracuse University, of the 233 students listed under separate courses, 50 are taking work in library economy; 275 students from the college of liberal arts are also taking work in education.

At Tulane University, 7 are enrolled in tropical medicine and hygiene and 22 are taking post-graduate medical work. The students mentioned under scientific schools are enrolled for engineering and sugar chemistry. The increase in numbers of the college of technology is due to changes made in the college, amounting practically to reorganization.

The 48 students listed under other courses at Washington University are in the school of social economy. The 319 students listed under extension and similar courses are taking Saturday courses for teachers and others in the college.

The 45 students listed under other courses at Western Reserve University are taking work in library economy. In Adelbert College, the college for women, the graduate school, the school of law and the library school, the annual tuition fee has been advanced from \$100 to \$125, and in the school of medicine from \$125 to \$150, these charges going into effect this year. The loss in enrollment in the school of law is

due to the graduation of the last class received upon the non-graduate basis, all classes now being upon the college graduate basis. The change from the non-graduate to the graduate basis is seen to have taken effect with but a small loss in numbers. The loss in enrollment in the school of medicine is more apparent than real, the difference being caused largely by the recent yearly graduation of two classes,—Ohio Wesleyan University and Western Reserve University,—and the reception of one class on the Western Reserve University college graduate basis only.

Of the 45 students listed under other courses at the University of Wisconsin, 43 are enrolled in library economy and 2 are taking work in public health. The 40 students in pharmacy include 24 students in a two-year pharmacy course, for which four years of high school preparation is not required. A forest rangers' course consisting of 12 students began work at the university January 7, 1913. These students did not complete their field work until November 30.

The most considerable increase in enrollment at Yale University is in the college. The entering classes in the law and medical schools also show noticeable increases and indicate that the requirement of a college degree for admission to the law school and of two years of college work for admission to the medical school, adopted two years ago, is being appreciated by the best grade of students. The only noticeable falling off is in the graduate school. This is due exclusively to the new requirement of two years' work for the master of arts degree instead of one year, as in force at Yale prior to 1912 and still the custom at almost all the American universities.

RUDOLF TOMBO, JR.

COLUMBIA UNIVERSITY

*THE MASSACHUSETTS INSTITUTE OF
TECHNOLOGY AND HARVARD
UNIVERSITY¹*

In this agreement, "the institute" means the Massachusetts Institute of Technology, and "the university" means Harvard University. It is understood that any action of the president and fellows of Harvard College shall require the consent of the board of overseers wherever such consent is necessary under the laws governing the university.

I. The university and the institute shall be unaffected in name, organization, title to and rights over property, or in any other way not specifically mentioned in this agreement.

II. The university and the institute shall cooperate in the conduct of courses leading to degrees in mechanical, electrical, civil and sanitary engineering, mining and metallurgy, and in the promotion of research in those branches of applied science. The courses and research shall be conducted in accordance with the provisions of this agreement and on the site in Cambridge recently acquired by the institute bordering on Massachusetts Avenue and the Charles River Embankment or on any other site that may be agreed upon should future conditions render an extension or change of site desirable.

III. Subject to the reservations hereinafter set forth the university shall devote to the purposes referred to in Section II. the net income of all funds that are credited on its books to the Lawrence Scientific School; also the use of all machinery, instruments, and equipment that are suited to these purposes and that the university does not in its opinion need more urgently for other purposes; also not less than three fifths of the net income of the Gordon McKay Endowment; also the income of all property that it may acquire hereafter for the promotion of education or research in the branches of applied science referred to in Section II.; also such further sums as it may from time to time feel able to contribute.

IV. Subject to the reservations hereinafter

¹ Agreement ratified by the corporations of both institutions on January 6.

set forth, the institute shall devote to the purposes referred to in Section II. all funds, or the income of all funds, that it now holds or hereafter acquires for the promotion of education or research in the branches of applied science mentioned in that section, and in addition to this as much of the funds, or income of funds, that it holds for general purposes as is not in its opinion more urgently required for other purposes.

V. Students' fees for courses in the branches of applied science mentioned in Section II., shall be devoted to the purposes referred to in that section. These fees shall for the first ten years be deemed to be contributed by the two institutions in the proportion of the numbers of the students following these courses in the institute and in the university's graduate schools of applied science, respectively, during the year 1913-14. At the end of ten years a different arrangement shall be made, if, in the opinion of the two corporations, it appears to be more equitable. The fees of students pursuing courses in the subjects referred to in Section II. in the university's graduate schools of applied science at the time when this agreement is adopted shall be unaffected by any change brought about by this agreement. For all other students the amount of the fees for complete courses leading to those degrees of the institute and of the university that are granted through the operation of this agreement shall be \$250 per annum until changed by agreement between the two corporations. The amount of fees for partial courses and for research shall be determined as may be agreed upon from time to time.

VI. The funds available for education and research in the branches of applied science referred to in Section II. shall be expended through the bursary of the institute in the payment of salaries, the maintenance of scholarships, the care of grounds, and the erection and maintenance of buildings and equipment or otherwise as may be agreed upon from time to time, it being expressly provided that all proposed appropriations shall be approved by the corporation that supplies the funds, and that buildings shall be erected only

from the share of the funds supplied by the institute.

VII. All members of the instructing staff in the departments of mechanical, electrical, civil and sanitary engineering, mining and metallurgy, who give instruction in courses leading to the degrees both of the university and of the institute, shall be appointed and removed by the corporation that pays their salaries after consultation with the other corporation.

VIII. All students registered at the institute in the various numbered professional courses covered by Section II. that lead to degrees of the university shall be deemed to be prospective candidates for such degrees unless they signify a contrary intention, and shall be entitled to the same rights and privileges as students in the professional schools of the university.

IX. The president or acting president of the institute shall be the executive head for all the work carried on under this agreement. As an evidence of his responsibility in directing it he shall make an annual report to both corporations. When any future president or acting president is to be selected, the president or acting president of the university shall be invited to sit with the committee that recommends the appointment of a president or acting president to the corporation of the institute.

X. As soon as this agreement goes into effect, the faculty of the institute shall be enlarged by the addition thereto of the professors, associate professors and assistant professors of mechanical, electrical, civil and sanitary engineering, mining and metallurgy, in the university's schools of applied science. These persons shall acquire the titles and privileges of the same rank in the institute while retaining their titles and privileges in Harvard University, and the terms and conditions of their employment and their salaries shall be unaffected by the change. The professors, associate professors and assistant professors of the institute in the departments of mechanical, electrical, civil and sanitary engineering, mining and metallurgy, shall acquire

the titles and privileges of the same rank in Harvard University while retaining their titles and privileges in the institute, and the terms and conditions of their employment and their salaries shall be unaffected by the change. All professors, associate professors and assistant professors appointed under the operation of Section VII. shall have the titles and privileges of professors of the university and of the institute, including the right to benefit from the pension system of both institutions.

Additions to the faculty of the institute shall be made by the appointment of professors, associate professors or assistant professors, under the operation of Section VII., or by the corporation of the institute for other purposes. The faculty constituted as indicated above shall, subject to such directions as may be given by the corporation of the institute, prescribe the courses and conditions of entrance thereto leading to all degrees granted by the institute. The same faculty shall, subject to such directions as may be given by the corporation of the university, prescribe the courses and conditions of entrance thereto leading to all degrees granted by the university under the operation of this agreement.

XI. Degrees shall be conferred by the institute and by the university acting separately on the recommendation of the faculty referred to in Section X.

XII. It is expressly provided that, as regards the funds and property of the university and of the institute respectively referred to in Sections III. and IV., this agreement shall be subject to any special terms and requirements upon which such funds and property may be held; and any property or funds that may be held at any time by either corporation under such terms and restrictions as would prevent their use precisely as is indicated in this agreement, shall, nevertheless, be used by the two corporations respectively for the support, benefit or encouragement of a cooperative effort in the field of education and research in engineering and mining in such manner as may be permissible or in accordance with the trusts upon which they may be held.

XIII. Whereas, doubts might arise as to

the legal effect of an omission from this agreement of any provision for its termination, it is hereby provided that the agreement may be terminated either by the university or by the institute, but that no termination shall be made except upon notice from one party to the other of at least five years unless a shorter time be mutually agreed upon.

XIV. This agreement shall take effect when finally adopted and approved by the corporation and board of overseers of the university and the corporation of the institute; and the cooperation referred to in Section II. shall begin when the institute is ready to open courses in engineering and mining on the site in Cambridge mentioned in that section.

STATEMENT BY PRESIDENT LOWELL

FRIENDS of Harvard University and the Massachusetts Institute of Technology—and they have many friends in common—have long deplored the rivalry of two schools of engineering competing on opposite sides of a river. The disadvantages have been made even more evident by the decision of the institute to cross the Charles; but the difficulty of making an arrangement satisfactory to both parties has hitherto been very great, and in fact the obstacles to a combination between rival institutions supported by and serving the same community have been one of the grave defects of higher education in America. This difficulty seems at last to have been overcome here by a plan for cooperation in the conduct of one school of engineering and mining. The plan is favorable to both institutions. Both gain thereby. Which gains the most can probably not be determined, and certainly has not been computed, for the leading motive with the authors of the agreement has lain in another plane. Both institutions exist for the promotion of instruction and research. Each is a means to an end larger than itself, the welfare of the community as a whole; and that both acting in concert can further this end better than either working alone can not be doubted. By the combination of resources and momentum a school ought to be maintained un-

equalled on this continent and perhaps in the old world.

A. LAWRENCE LOWELL

STATEMENT BY PRESIDENT MACLAURIN

THE advantages of cooperation between the institute and Harvard have long been the subject of discussion. With reference to the present plan of cooperation, I beg to make the following statements:

1. The Honorable Richard Olney, in a carefully considered legal opinion, says "Cooperation between educational institutions for a legitimate purpose common to both is certainly not illegal and in this case wholly desirable. The 'agreement' seems to me to spell cooperation and nothing more, involves no merger of corporations or their property interests, and can be carried into effect without violation of charters or of the trusts upon which funds are held."

2. Its adoption by the corporation is unanimously recommended by the executive committee.

3. It is approved by each of the last five presidents of the Alumni Association, and by the president-elect. The president of the Alumni Association, Mr. Frederic H. Fay, writes: "I heartily commend this effort on your part, and I believe that when it is found that an agreement, such as you have proposed, can be carried out to the satisfaction of the authorities of both institutions, you will find that you have the great body of Tech Alumni behind you, and that you will have added to the prestige, and usefulness and strength of the institute."

4. It is approved by all the heads of the institute's departments that are directly affected and by all the other senior members of the faculty who have been consulted with reference to it.

5. It leaves the institute so entirely independent that it can appoint any officer or instructor that it pleases, it can appropriate its funds as it pleases, and it can make any regulations that it pleases with reference to the courses leading to its degree.

I believe that the adoption of this agreement is a forward step of very great import to the

future of education in this country. Incidentally, it would be of great advantage to each of the cooperating institutions, but it would be especially significant in the emphasis that it would give to the fact, so often overlooked, that educational institutions do not exist for themselves and that their sole duty is to make the best provision that can possibly be made for those who are rising to manhood and for their successors. Under the scheme of cooperation here proposed, it would be possible to maintain a much stronger school of applied science than either institution alone could furnish, and it would be possible to keep that school practically unrivalled in America—and indeed, in the world.

SCIENTIFIC NOTES AND NEWS

DR. BENJAMIN OSGOOD-PEIRCE, since 1888 Hollis professor of mathematics and natural philosophy in Harvard University, died from disease of the heart at his home in Cambridge on January 14.

DR. HERMAN M. BIGGS has been appointed by Governor Glynn to be commissioner of health for the state of New York.

DR. ERNEST RUTHERFORD, Langworthy professor of physics in the University of Manchester, has been made a knight.

IN the Academy of Sciences of St. Petersburg, Sir William Ramsay has been advanced from a corresponding to an honorary member.

AT the annual meeting of the Federation of American Societies for Experimental Biology, an organization which includes the Physiological Society, the Society of Biological Chemistry and the Society for Pharmacological and Experimental Therapeutics, held in Philadelphia, the following officers were elected: *President*, Dr. Graham Lusk, New York City; *Vice-president*, Dr. Carl Alsberg, Washington, D. C.; *Secretary*, Dr. P. A. Shaffer, St. Louis; *Treasurer*, Dr. D. D. Van Slyke, New York City, and councilors, Professor J. J. Abel, Baltimore, and Professor A. B. Macallum, New York, and Dr. T. B. Osborne, New Haven, Conn.

PROFESSOR W. B. CANNON, of Harvard University, was elected president of the American Physiological Society at the meeting in Philadelphia.

AT the thirtieth session of the American Association of Anatomists held in Philadelphia at the University of Pennsylvania the following officers were elected: *President*, Professor G. Carl Huber, University of Michigan; *Vice-president*, Professor Frederic T. Lewis, Harvard Medical School; *Secretary-treasurer*, Professor Charles R. Stockard, Cornell Medical College.

AT the meeting of the American Phytopathological Society recently held at Atlanta the following officers were elected: *President*, Dr. Haven Metcalf, Washington, D. C.; *Vice-president*, Dr. Frank D. Kern, State College, Pa.; *Counsellor*, Professor H. R. Fulton, West Raleigh, N. C.

A DINNER in honor of Dr. Livingston Farland, professor of anthropology in Columbia University, who has accepted the presidency of the University of Colorado, was held by his colleagues at the Faculty Club, Columbia University, on January 13.

THE following new appointments of members of the gardening staff at Kew are quoted in *Nature* from the *Kew Bulletin*: Mr. G. S. Crouch, to be assistant director of horticulture in the Egyptian department of agriculture; Mr. T. H. Parsons, to be curator of the Royal Botanic Gardens, Peradeniya, Ceylon, in succession to Mr. H. F. Macmillan, who has been appointed superintendent of horticulture in the department of agriculture, Ceylon; Mr. C. E. F. Allen, to be curator of the Botanic Garden, Port Darwin, Northern Territory, South Australia, in succession to Mr. N. Holtze, deceased.

MRS. AGNES CHASE, assistant in systematic agrostology, U. S. Department of Agriculture, has returned from Porto Rico where she has been collecting and studying grasses for about two months. Of the 123 species of grasses known from the island she obtained all but three, and about 40 additional species. *Arthrostylidium sarmentosum* Pilger, a climbing

bamboo, known only in the sterile condition, was obtained in flower.

AN alumni chapter of the Sigma Xi has been planned in Washington, D. C., which will be known as the "D. C." Chapter. An organizing committee consisting of Marcus Benjamin (Columbia), *Chairman*; M. W. Lyon (Brown), *Secretary*; Paul Bartsch (Iowa), B. W. Everman (Indiana), Edmond Heller (Stanford), L. O. Howard (Cornell), F. J. Katz (Chicago), W. R. Maxon (Syracuse), T. S. Palmer (California), J. E. Pogue (Yale) and B. H. Ransom (Nebraska) are about to apply for a charter. As there are over 200 members in Washington it is expected that a large and flourishing chapter will be formed.

THE Norman W. Harris Lectures for 1913-1914 will be delivered by Dr. Edwin Grant Conklin, professor of zoology at Princeton University, on the subject, "Heredity and Environment in the Development of Men," February 9 to 14 inclusive, Northwestern University, Evanston.

AT the annual meeting of the Washington Academy of Sciences held at the Cosmos Club on January 15, the retiring president, Dr. O. H. Tittmann, delivered an address on "Our Northern Boundaries."

PROFESSOR EDWARD KASNER, of Columbia University, on January 17 gave a lecture at Princeton University on "Elements of Infinite Order and the Geometry of Divergent Power Series."

AT an open meeting of the Sigma Xi Society at Case School of Applied Science, Cleveland, Ohio, on January 14, Dr. O. P. Hay, research associate of the Carnegie Institution of Washington, D. C., lectured on "The Ice Age of North America and its Remarkable Animals."

THE first of a series of lectures on practical conservation and industrial questions, given under the auspices of the Ohio State University for the benefit of citizens of the state, was delivered January 8 by Professor C. E. Sherman, of the department of civil engineering. His theme was the regulation of streams, with special reference to floods.

ON January 6 Associate Professor Frederick Starr, of the department of sociology and anthropology in the University of Chicago, begins a course of five illustrated lectures on the general subject of "Japan: The Land of the Rising Sun" at the Abraham Lincoln Center of the University Lecture Association in Chicago. The subjects of the individual lectures are as follows: "The Life of the Japanese," "Japanese Religion," "The Hairy Ainu of Japan," "Korea: The Land of the Morning Calm," and "Far Eastern Questions."

PROFESSOR ALBION WOODBURY SMALL, head of the department of sociology and anthropology in the University of Chicago, delivered on December 27, at the eighth annual meeting of the American Sociological Society in Minneapolis, his address as the retiring president of the society. The address, which was on "Problems of Social Assimilation," was given at a joint meeting of the American Sociological Society and the American Economic Association.

MR. W. POPPLEWELL BLOXAM, formerly professor of chemistry in Presidency College, Madras, and the author of papers on the production and chemistry of indigo, died on December 26, aged fifty-three years.

DR. GEORGE WILLIAM PECKHAM, librarian of the Milwaukee Public Library, known for his important contributions to entomology, died on January 11, aged sixty-eight years.

EDMUND B. HUEY, PH.D., died in Connell, Washington, on December 30, 1913. Dr. Huey had been in the west for a year trying to regain his health. He had previously been associated with Dr. Adolf Meyer, at the Johns Hopkins Hospital. He was the author of a book on "The Psychology of Reading" and another on "Mentally Defective Children," and was one of the foremost leaders in the more recent study of mentally defective children. He spent a year studying defective children at the State Home for the Feeble-minded at Lincoln, Ill., and had previous to this spent two years with Janet in Paris. He was preparing a book on clinical psychology, but about six months before his death the notes and what

manuscript he had prepared, the accumulation of perhaps ten years, were completely destroyed by fire.

As the result of infection by glanders bacilli while working in the laboratory, Mr. A. M. Jansen, instructor in the veterinary college of Ohio State University, died on January 4.

THE United States Geological Survey is in receipt of a cablegram from St. Petersburg in which "the Geological Survey, of Russia, announces with profound grief the unexpected death of its director, Theodosie Tchernycheff, in the fifty-seventh year of his life."

A MEMORIAL fund raised by the friends of the late Humphrey Owen Jones, F.R.S., fellow of Clare College, who, with his wife, was killed in the Alps in August, 1912, has been gratefully accepted by the university, and a Humphrey Owen Jones lectureship in physical chemistry has been established.

THE U. S. Civil Service Commission announces a competitive examination for research chemist, to fill two vacancies in this position in the Bureau of Animal Industry, Department of Agriculture, Washington, D. C., at salaries of \$1,800 a year.

THE completion of the 30-inch photographic refractor of the Allegheny Observatory has been long delayed by the difficulty of manufacturing suitable glass disks. These have now been delivered by Schott and Co., of Jena, Germany, and it is expected that the telescope will be in use early next fall.

At a recent meeting of the board of trustees of the University of Illinois, Mr. R. Y. Williams was appointed director of the miners' and mechanics' institutes, which are to be established under the direction of the department of mining engineering. Authority for the establishment of these institutes was granted by an act of the state legislature in 1911, but no appropriation was made to carry out the authorization until the latter part of the recent session of the legislature, at which time an appropriation of \$15,000 per annum was made. The purpose of the miners' and mechanics' institutes is somewhat similar to

that of the farmers' institutes, but their specific purpose is to assist men who are preparing themselves to pass the tests required by the state before they can hold official positions about the mines. Mr. Williams graduated from Princeton University in 1901.

It is stated in the *British Medical Journal* that Dr. L. W. Sambon, who left England in August last to investigate pellagra in the West Indies, returned to London at the beginning of January. By invitation he first proceeded to the United States of America, and in Spartanburg, Columbia and Charleston he met several of the men who have recently devoted themselves to the study of pellagra, and delivered addresses before medical societies in these cities. Dr. Sambon found that in the United States the interest in the disease was very keen, owing no doubt to the evidences of the existence of pellagra to a serious extent in many parts of the country. As is well known, Dr. Sambon's opinion is that pellagra is not due to the consumption of maize, whether diseased or sound, but that it is caused by an infection brought about most probably by a fly. His investigations in southern and eastern Europe suggested that the intermediary was a simulum, an insect closely allied to the group represented by the sandfly. In the United States Dr. Sambon found many men ready to accept this hypothesis, and was greatly impressed with the work which was being carried out by the Thompson-MacFadden Pellagra Commission in South Carolina. After leaving the North American continent he proceeded to the West Indies, where he visited Jamaica, Antigua, Barbados, Trinidad, Grenada, St. Vincent and other islands. In the hospitals, asylums and rural districts he met with many cases of pellagra, and proved the existence of the disease in several areas in which its presence had previously been unknown. Dr. Sambon also visited British Guiana, and found pellagra along the coast from the Demerara to the Berbice rivers. In part of his trip Dr. Sambon was accompanied by Captain Siler, U. S. Army, chief of the American Pellagra Commission, and by Mr. Jennings, of the Entomological Bureau, Washington, D. C.

SEVENTY-FIVE per cent. of a highly valuable fertilizing material in the form of tankage and blood from the country slaughter of food animals is being wasted throughout the country districts, according to a recent bulletin of the Department of Agriculture. Tankage, a product of slaughter houses consisting of such waste material as bones, horns, hoofs, hair, etc., contains a large percentage of nitrogen and other products used in commercial fertilizer and in the larger packing houses is carefully saved. In country killing, however, only 25 per cent. of the tankage and blood are saved for fertilizer. The nitrogen content of tankage is said to vary from 5 to 8 per cent. and its phosphoric acid content between 5 and 12 per cent. Dried blood is perhaps the richest in nitrogen of all the organic materials used in the fertilizing industries. Unadulterated blood when quite dry contains 14 per cent. of nitrogen, but as obtained on the market its content varies from 9 to 13 per cent. From the figures estimated by the Bureau of Animal Industry, Department of Agriculture, as representing the total slaughter of cattle, calves, swine, and sheep in the United States, in 1912, it has been calculated that if all the materials rendered available by this slaughter had been saved and converted into tankage and dried blood, they would have produced 222,535 tons of tankage and 79,794 tons of dried blood. The introduction of a cooperative system among American farmers undoubtedly would result in an increased utilization of blood and tankage for fertilizing purposes. In Denmark country killing is being practised on a cooperative basis in small country abattoirs, and the blood is carefully preserved.

UNIVERSITY AND EDUCATIONAL NEWS

A NEW art building to cost \$125,000 is now guaranteed for Oberlin College. The names of the donors are at their request withheld.

MR. F. W. BRADLEY has offered a gift of \$1,000 a year for at least ten years to endow a loan fund for students in the college of mining of the University of California. Both

principal and income of the gift are to be available for these loans.

HARVARD UNIVERSITY has received the sum of \$7,500 with which to establish a scholarship in memory of the late Francis Hardon Burr, '09. This fund is to be known as the Francis H. Burr 1909 Fund, and the yearly income therefrom is to be used in helping deserving undergraduates who combine as nearly as possible Burr's remarkable qualities of character, leadership and athletic ability. The fund was raised principally from the members of Burr's class, but some of his older friends also contributed.

By the will of the late Miss Emily M. Easton £10,000 are bequeathed to the Durham College of Medicine, Newcastle, and £5,000 to Armstrong College.

THE dedication at the winter convocation of the University of Chicago of the new addition to the Ryerson Physical Laboratory marks a great increase in the research facilities of the university in the field of physics. The new addition is connected with the original building by corridors and consists of a basement and three floors. It contains the liquid air and refrigerating plants, the dynamos and motors, the machine and instrument shops, and the switchboard for distributing electric currents of all kinds to all parts of both buildings. It has besides two large student laboratories, a lecture room and four research rooms. The old Ryerson Laboratory has been renewed by the installation of a modern electric light and power system of unusual completeness, by the insertion of new steel-concrete floors in all the ground-floor rooms, and by the remodeling of the entire basement into a series of special research rooms, of great value where freedom from vibration and constancy of temperature are required.

THE associates of Radcliffe College have elected Miss Bertha May Boody to succeed Miss Mary Coes as dean of the college. Miss Boody is a native of Brookline and received the A.B. degree from Radcliffe in 1899 and the A.M. degree from Columbia in 1912. She has

studied for one winter in the American School for Classical Studies in Rome, and for one summer in the University of Cambridge, England.

PROFESSOR WALTER MULFORD, of Cornell University, has been appointed head of the new department of forestry in the University of California. His duties will begin with August 1 next. Since there are 29,000,000 acres of national forest in California, besides vast areas of forest privately owned, the subject is one of great importance there. Dr. Patrick Beveridge Kennedy has been appointed assistant professor of agronomy. Dr. Calvin O. Esterly has been appointed as a biologist in the Scripps Institution for Biological Research at La Jolla.

MR. J. J. GALLOWAY, Ph.D. (Indiana), has been appointed instructor in geology at Indiana University.

MR. HALBERT P. BYBEE, M.A. (Indiana), has been appointed instructor in geology at the University of Texas.

MR. J. C. JOHNSON has been appointed to the chair of general biology, botany and zoology, at Auckland University College, in succession to Professor A. P. W. Thomas.

DISCUSSION AND CORRESPONDENCE

COLUMBIUM VERSUS NIOBIUM

At a meeting of the Council of the International Association of Chemical Societies in Brussels, last September, a committee on inorganic nomenclature, among other recommendations, endorsed the name and symbol "niobium" and "Nb," for the element which was originally named columbium. As this recommendation is historically erroneous, a brief statement of the facts appears to be desirable.

In 1801, Hatchett, an English chemist, analyzed a strange American mineral, and in it found a new metallic acid; the oxide of an element which he named columbium. A year later, Ekeberg, in Sweden, analyzed a similar mineral from Finland, and discovered another element, which he called tantalum. Wollas-

ton, in 1809, undertook a new investigation of these elements, and concluded that they were identical; a conclusion which, if it were true, would have involved the rejection of the later name, and the retention of the earlier columbium. The accepted rules of scientific nomenclature make this point clear.

For more than forty years after Hatchett's discovery, both names were in current use; for although Wollaston's views were accepted by many chemists, there were others unconvinced. In 1844, however, Heinrich Rose after an elaborate study of columbite and tantalite from many localities, announced the discovery of two new elements in them, niobium and pelopium. The latter supposed element was afterwards found to be non-existent, but the niobium was merely the old columbium under a new name. That name in some mysterious manner was substituted by the German chemists for the original, appropriate name, and has been in general use in Europe ever since. In America, the name columbium has been generally preferred, and was formally endorsed by the Chemical Section of the American Association for the Advancement of Science more than twenty years ago. In England, also, columbium is much used, as, for example, in Roscoe and Schorlemmer's "Treatise on Chemistry," Thorpe's "Dictionary of Applied Chemistry," and the new edition of the *Encyclopaedia Britannica*.

The foundation of Rose's error seems to have been an uncritical acceptance of Wollaston's views; for he speaks of all the minerals he studied as tantalite. He also, at least in his original memoir, claims that the atomic weight of niobium is greater than that of tantalum, and here he was obviously wrong.

In short, the name columbium has more than forty years priority, and during that interval was accepted by many chemists, and was more or less in current use. To employ the name niobium is not only unhistorical, but it is also unfair to the original discoverer, meaningless, and without any justification whatever. Furthermore, it injures the splendid reputation of Rose, for it perpetuates and emphasizes one of his few errors. The recom-

mendation of the committee above mentioned should not be accepted, for it is opposed to the established rules of priority.

F. W. CLARKE

THE CYTOLOGICAL TIME OF MUTATION IN TOBACCO

In the current volume of *SCIENCE*, p. 35, Hayes and Beinhart after describing the origin of a many-leaved variety of Cuban tobacco by mutation say:

This mutation must have taken place after fertilization, *i. e.*, after the union of the male and female reproductive cells. If the mutation had taken place in either the male or female cell before fertilization, the mutant would have been a first generation hybrid, and would have given a variable progeny the following season.

Is it not equally probable that the mutation occurred in an egg-cell which then developed without fertilization? Parthenogenesis is known to occur in tobacco, and mutation in a growing or immature germ-cell seems inherently more probable than in a fully formed and fertilized one. Perhaps the behavior of the additional mutants obtained in 1913 will throw light on the matter.

BUSSEY INSTITUTION,

January 2, 1913

SCIENTIFIC BOOKS

Analytical Mechanics. By HAROUTUNE M. DADOURIAN, M.A., Ph.D., Instructor of Physics in the Sheffield Scientific School of Yale University. D. Van Nostrand Company. Price \$3.00.

In his preface, the author states that his "work is based upon a course of lectures and recitations which the author has given, during the last few years, to the junior class of the Electrical Engineering Department of the Sheffield Scientific School." We expect this book to contain, therefore, several topics of special interest to students of electricity. We find a chapter devoted to "Fields of Force and Newtonian Potential," one to "Periodic Motion," one to "Energy" and one to "Work." But, as the author states, "In order to make the book

suitable for the purposes of more than one class of students more special topics are discussed than any one class will probably take up. But these are so arranged as to permit the omission of one or more without breaking the logical continuity of the subject."

The author himself is a physicist, and perhaps he intends this book to be suitable for classes in physics. The book seems to be written from the standpoint of the physicist rather than from the standpoint of the engineer. If this book is intended for the students of civil and mechanical engineering, then it must be said it has no advantage over the number of books already in the field. I doubt if it is even as suitable.

Judging from the recent discussions concerning the teaching of mathematics and mechanics, it seems that the successful book has not yet been written. Possibly the book everybody is looking for must be written on a new plan. To say that an author deviates from the generally acknowledged plan need not be a criticism of his book. Dr. Dadourian makes his volume unique in several ways, but I doubt if it will stand the test.

In the first place, he seems to avoid the graphical treatment. The modern tendency seems to be to emphasize this phase of the subject.

The question of "units" is always a source of contention between the physicist and the engineer. The absolute system of units is certainly the most logical. To the engineer, however, it is not a question of logic, but of adaptability.

Another departure from the usual mode of procedure in modern elementary text-books in mechanics is the extent to which he makes use of "vector addition." The first chapter is devoted to the subject of the "addition and resolution of vectors." On page 10 he gives the analytical expression for the resultant of any number of vectors, and the resolution of a vector into its three rectangular components. This section is made the basis of his whole book so far as the composition and resolution of vector quantities (forces, moments, couples, etc.) are concerned. All he needs to say is,

that a couple (for instance) is a vector and the desired equations follow at once. If economy of space means "economy of thought" then the author has made his book very simple indeed. To prove the equivalence of couples it is only necessary to state: "Two couples are equal when the vectors which represent their torques are equal in magnitude and have the same direction." This follows at once from his definition of a vector.

He states in his preface "that a subject like mechanics should start with a few simple laws and the entire structure of the science should be based upon them. In the present work the following law is made the basis of the entire subject:

"To every action there is an equal and opposite reaction, or, the sum of all the actions to which a body or a part of a body is subject at any instant vanishes." He further states that thus the "fundamental principle of mechanics is put in the form of a single law, which is equivalent to Newton's laws of motion and which has the advantages of the point of view involved in D'Alembert's principle."

Here is a unique departure for an elementary book. Does he mean to say that this law, whatever it may mean, is the only assumption he will make and that Newton's laws of motion as usually given will not be made use of? If he does, he completely fails. On page 16, he introduces the conception of "force" as an "action," and without any hesitation applies vector addition to a system of forces. What is he doing here, but assuming the "parallelogram of forces" in its most general form. On page 102 he assumes that a force is proportional to the acceleration produced. This assumes Newton's second law of motion. In fact he makes more assumptions than are usually made in elementary text-books of mechanics.

What about the law itself? The first part of the law is clear. "To every action there is an equal and opposite reaction" is nothing but Newton's third law of motion. The word "or" leads us to think that the second part means the same thing as the first part. On page 15 he states that "The fundamental law

of mechanics' is known as the law of *action and reaction*." He then states Newton's third law and gives the following illustration. "Let us apply this law to the interaction between a book and the hand in which you hold it. Your hand presses upward upon the book in order to keep it from falling, while the book presses downward upon your hand. The law states that the action of your hand equals the reaction of the book and is in the opposite direction. The book reacts upon your hand because the earth attracts it. When your hand and the earth are the only bodies which act upon the book, the action of your hand equals and is opposite to the action of the earth. In other words, the sum of the two actions is nil. Generalizing from this simple illustration, we can put the law into the following form:

"To every action there is an equal and opposite reaction, or the sum of all the actions to which a body or a part of a body is subject at any instant vanishes."

Now does he mean to say that the pressure of the hand on the book and the force of gravity acting on the book are equal because they are action and reaction? If he does he errs. *They are not action and reaction and are equal only in case equilibrium exists.* He has said nothing about equilibrium and if he does not mean this then what does he mean?

On page 100 he takes up the subject of "motion of a particle." Here he says that "we must extend the meaning of the term *reaction* so as to include a form of reaction which is known as *kinetic reaction*. In his illustration we see that by *kinetic reaction* he means the so-called *force of inertia*. We also see that he considers kinetic reaction as a real force. To this, serious objections can be raised. The meaning of the second part now becomes clear. It is simply *D'Alembert's Principle*—"The impressed forces together with the reversed effective forces form a system in equilibrium."

I fail to see, however, the advantage of assuming D'Alembert's principle as a fundamental law of mechanics, especially since he finds it necessary, in reality, to assume all of Newton's laws besides. Moreover the law itself

as he states it, and his applications of it, are rather confusing. It would be difficult indeed to put D'Alembert's principle in words so that a student at the beginning of his study of mechanics could grasp its significance. Any attempt would be apt to confuse rather than help the student.

Space will not permit me to go into further detail. To be brief, he seems inclined to introduce new difficulties, and to cover up the old ones. The book is not free from loose reasoning.

E. W. RETTGER

CORNELL UNIVERSITY

Conservation of Water. By WALTER McCULLOH, C. E. Addresses delivered in the Chester S. Lyman lecture series, 1912, before the senior class of the Sheffield Scientific School, Yale University. New Haven, Yale University Press; London, Humphrey Milford, Oxford University Press. Cloth, $6\frac{1}{2} \times 9\frac{1}{2}$ in. Pp. x + 99; 39 illustrations. \$2. Postage, 15 cents.

At a time when the question of our water resources and a national policy regarding them is becoming a matter of increasing importance this book is very opportune. The lectures printed therein cover the following topics:

The first chapter considers the desirability of proper handling of our water supplies and the questions of legal jurisdiction over them. Then follows a chapter on the economic, hydrographic, topographic and geologic data necessary for an intelligent handling of the problem in any case. The third chapter gives some very interesting information in regard to the water power of the United States, both developed and undeveloped, with some statistics that are hard to collect otherwise. The value of storage reservoirs in connection with power developments is shown. The next chapter treats of water supplies for municipalities and the problems of sanitation and drainage. The last chapter describes in detail the water resources of New York state and the present important developments.

This is not a book for a specialist, already

well informed in hydraulics, nor is it well adapted for use as a text-book for students. But for all readers who are interested in water resources and related problems it is a book that can be read with profit. It should be of especial value to the non-technical man who desires a broad understanding of the engineering principles involved.

R. L. DAUGHERTY

CORNELL UNIVERSITY

Stuttering and Lipping. By E. W. SCRIPTURE. New York, The Macmillan Co. 1912. Pp. xiv + 251.

After many years of clinical work and private practise in the treatment of speech defects, Dr. Scripture has here written down many of his observations regarding the causes, symptoms and treatment of stuttering and chronic mispronunciation. "As a cause of stuttering a "general anxiety neurosis" is emphasized but the author avoids much elaboration of this topic.

In the chapter on symptoms some etiology is necessarily considered and many interesting kymograph records of respiration, vocal and articulatory movements are reproduced. The method of taking these records is well illustrated by photographs, and their significance is discussed in the text. The treatment outlined is perhaps the most valuable contribution in the book and is systematically referred to the preceding diagnosis. The exercises in voice modulation—a method of treatment largely original with the author—are carefully described. Psychoanalysis and suggestion are dealt with briefly.

The second part of the book treats of lipping, as it is of negligent, organic or neurotic origin. The mouth positions for articulating the different vowel and consonant sounds are indicated by diagrams, "palatograms" and photographs. Some valuable methods for inducing the patient to attain the proper positions are given. At the end of the book are fifty pages of exercises to be used in the treatment of both stuttering and lipping.

SPECIAL ARTICLES

SOME PHYSIOLOGICAL OBSERVATIONS REGARDING
PLUMAGE PATTERNS¹

THIS study was undertaken with the object of carrying the analysis of the genetic factors for color pattern somewhat farther than has hitherto been done. In many forms of domestic poultry the plumage of particular parts of the body displays on each feather a definite and regular pattern. Experimental studies show that these patterns are inherited in a clean-cut Mendelian manner. In the case of the Barred Plymouth Rock color pattern, which has been more thoroughly studied in regard to its inheritance than any other single plumage pattern in birds, extensive investigations in this laboratory and elsewhere indicate that this barred pattern is represented in the gametes by a single Mendelian factor or gene. The manner in which this gene operates physiologically presents a problem of great interest, since it involves an element of morphogenetic localization.

With a view of getting further light on this matter a study has been made of the successive regeneration of feathers, in which special attention has been paid to the comparison of the pattern shown in the regenerates and in the original feather. It is the purpose here to make a preliminary statement regarding this work and some of the results obtained, to be followed later by a detailed account.

A word should be said in regard to one point of technique, since this made possible the carrying on of the investigation in a precise and critical manner. The point referred to is the method used for the identification of the individual feather follicle. If the feathers successively produced in the same follicle are to be compared, it is necessary that this particular follicle shall be capable of absolutely sure identification at any time, whether or not there is a feather present. This result was

very satisfactorily attained by tattooing with india ink a circle around each follicle chosen for study. These tattoo marks are permanent throughout the life of the individual and make it possible to find at any time the follicle which one is studying.

A few of the more important results which have been obtained from this study, which has now been in progress about a year and a half, may be here set forth, as follows:

1. All feather follicles are not capable of continually producing successive feathers for an indefinite time. In the case of the general body plumage a feather is usually not regenerated more than about three times. The precise number of successive regenerations varies with different birds and different feathers. Wing primaries seem to possess the maximum regenerative capacity. After about the third removal in the case of body feathers the follicle usually remains in a perfectly quiescent condition, taking no steps whatever toward the regeneration of a new feather.

2. This failure to regenerate is, however, very definitely related to the natural moult of the bird, and in the following way. A follicle which has been absolutely inactive for a long period of time (*e. g.*, six months) preceding the natural autumn moult of the bird produces a new feather in connection with the moult, in the same manner as does any other follicle of the body. In other words the process of natural moulting reactivates the follicle which had been brought into a quiescent state by successive feather removal.

3. The precise pattern exhibited by a particular feather is, in the usual course of events, reproduced each time a feather is produced by that follicle with extreme fidelity of detail. If, however, the feather is removed from the follicle as soon as it is fully grown, thus forcing continued regenerative activity of the follicle, the pattern tends progressively to be broken up, and probably will ultimately be entirely lost as a definite pattern. The experiments have not yet gone far enough to enable us to speak positively on this latter point. A progressive breaking up of an originally definite pattern is, however, very clearly

¹ Papers from the Biological Laboratory of the Maine Agricultural Experiment Station, No. 60. This paper was read at the meeting of the American Society of Naturalists in Philadelphia, December 31, 1913.

shown in a number of cases.² The behavior of the color pattern in successively regenerated feathers suggests, as a working hypothesis, that the pattern factor or gene is possibly represented in each follicle by a strictly limited amount of material, and that when this is used up the pattern is lost.

4. The secondary sexual feathers of the male, such as the saddle hangers, only appear as adult plumage. The same follicles which bear these feathers produce, as juvenile plumage, undifferentiated body feathers. The formation of these secondary sexual feathers is not necessarily dependent upon any normal moult. If the juvenile feather is removed from the follicle the next feather produced by that follicle will be the secondary sexual feather, and not a feather of the juvenile type. After that all further regenerations are of the sexually differentiated feather.

These investigations are being continued. A complete report, with illustrations, covering the progress of the work to date will shortly be published elsewhere.

RAYMOND PEARL,
ALICE M. BORING

THE AMERICAN SOCIETY FOR PHARMACOLOGY AND EXPERIMENTAL THERAPEUTICS

THE fifth annual meeting of the Pharmacological Society was held in Philadelphia on Monday and Tuesday, December 29 and 30, at Jefferson Medical College and the University of Pennsylvania. The scientific meetings were auspiciously inaugurated by a joint session of the three societies which form the Federation of American Societies for Experimental Biology, comprising the Physiological Society, the Society of Biological Chemists and the Pharmacological Society. The program of this joint meeting on Monday morning was opened by a short address of the president of the Physiological Society, Dr. S. J. Meltzer, as chairman of the federation. The title of his address was "Theories of Anesthesia."

The following papers were read and discussed: "Phlorhizin Glycosuria before and after Thyroidectomy," by Graham Lusk.

"Studies in Diabetes: (1) The Effect of Different Compounds of Glycogenesis; (2) The Mechanism of Antiketogenesis," by A. J. Ringer and E. M. Frankel (by invitation).

² Some of which were shown in the charts used in connection with the reading of this paper.

"Some Problems of Growth: (a) The Capacity to Grow; (b) The Role of Amino Acids in Growth," by L. B. Mendel and T. B. Osborne.

"Further Studies in the Comparative Biochemistry of Purine Metabolism," by Andrew Hunter.

"Changes in Fats during Absorption," by W. R. Bloor.

"Immunization against the Anti-coagulating Effect of Leech Extract," by Leo Loeb. (Read by title.)

"Anaphylaxis in the Cat and Opossum," by C. W. Edmunds.

"Vivdiffusion; Report on Preliminary Results," by J. J. Abel, L. S. Rowntree and B. B. Turner.

"A Method of Dialyzing Normal Circulating Blood and Some of Its Applications," by C. L. V. Hess (by invitation) and H. McGuigan.

"A Biological Test for Iodine in the Blood," by A. Woelfel and A. L. Tatum (by invitation).

"Further Studies of the Excretion of Acids," by L. G. Henderson and W. W. Palmer (by invitation).

The second scientific session was also held at Jefferson Medical College on Monday, December 29, from 2 to 5 P.M., and the following papers were read:

"Uranium Glycosuria," by G. B. Wallace and H. B. Meyers.

"A Comparative Study of the Vascular Response of the Kidneys in Animals Nephritic from Uranium Nitrate," by W. deB. MacNider.

"The Production of Glycosuria by Zinc Salts," by W. Salant and M. Kahn.

"Further Observations on Caffeine Glycosuria," by W. Salant and M. Kahn.

"Studies upon the Long-continued Feeding of Saponin," by C. L. Alsberg and C. S. Smith.

"The Effect of the Inhalation of Ether upon the Irritability of the Voluntary Peripheral Motor Mechanism," by J. Auer and S. J. Meltzer.

"The Irritability of Muscle and Motor Nerve in Chloroform Anesthesia," by T. S. Githens and S. J. Meltzer.

"The Cessation of Respiration in Deep Ether Anesthesia and its Possible Relation to the Action of Ether upon the Peripheral Motor Mechanism," by T. S. Githens and S. J. Meltzer.

"The Anesthetic Tensions of Ether Vapor for Man," by W. M. Boothby (by invitation).

"Studies in the Absorption of Drugs," by R. A. Hatcher and Cary Eggleston.

"Fatal Action of Magnesium Sulphate by Absorption from the Intestines," by J. Auer and S. J. Meltzer.

"Liberation of Formaldehyde from Hexamethylenamine in Pathological Fluids," by P. Hanzlik.

The third scientific session was held on Tuesday, December 30, from 9 to 12 M., in the engineering building of the University of Pennsylvania, and the following papers were presented and discussed:

"On Certain Effects of Digitalis Administration on the Human Heart" (with lantern demonstration), by A. E. Cohn and F. R. Fraser (by invitation).

"Quantitative Studies of Vagus Stimulation and Atropin," by J. D. Pilcher.

"Experiments on the Cardiac Action of Camphor," by O. H. Plant.

"The Action of Sodium and Potassium Iodide on the Heart and Blood Vessels," by I. D. Macht (by invitation). (Read by title.)

"The Influence of Sodium Tartrate on the Circulation," by W. Salant and C. S. Smith.

"The Pharmacological Action of Tetra-methylammonium Chloride on the Circulation and Respiration," by A. S. Loevenhart.

"Two Types of Periodic Respiration Produced by Morphin," by H. G. Barbour.

"The Pharmacological Action of Certain Substances on the Lungs and Respiration," by D. E. Jackson.

"Some Further Observations on Trypan-red Iodine Compounds," by P. A. Lewis and R. B. Krauss.

"Clinical Studies with Caffein," by Lester Taylor (by invitation).

"Further Observations on the Action of Ergot," by W. Salant and S. Hecht.

"The Toxicity of Tin," by W. Salant and C. S. Smith.

On Tuesday afternoon, December 30, the three societies forming the federation held a joint meeting at the medical laboratories of the University of Pennsylvania. At this meeting only demonstrations were given and of these the demonstration of Drs. Abel, Rowntree and Turner was especially beautiful. The titles were as follows:

"The Influence of the Vagi on Renal Secretion," by R. G. Pearce.

"Stimulation of the Semi-circular Canals," by F. H. Pike.

"Demonstration of Vividiffusion," by J. J. Abel, L. G. Rowntree and B. B. Turner.

"The Determination of Blood Sugar," by P. A. Shaffer.

"Intestinal Peristalsis in Homarus," by F. R. Miller.

"Methods for Studying the Pharmacology of the Circulation," by C. Brooks.

"The Contour of the Intraventricular and the Pulmonary Arterial Pressure Curves by Two New Optically Recording Manometers," by C. J. Wiggers.

"Some Time-saving Laboratory Methods," by C. C. Guthrie.

"A Graphic Method for Recording the Coagulation of Blood," by W. B. Cannon and W. K. Mendenhall (by invitation).

"Some Mutual Relations of Oxalates, Salts of Magnesium and Calcium; Their Concurrent and Antagonistic Actions," by F. L. Gates and S. J. Meltzer.

"A Method for Obtaining Successive Contrast of the Sensations of Hunger and Appetite," by A. J. Carlson.

"Further Observations of the Pyramidal Tracts of the Raccoon and Poreupine," by S. Simpson.

"A New Apparatus for Demonstration of the Dioptries of the Eye and the Principles of Ophthalmoscopy and Retinoscopy," by A. Woelfel.

"Simple Experiments on Respiration for the Use of Students," by Y. Henderson.

"Convenient Modification for Venous Pressure Determinations in Man," by R. D. Hooker.

"Device for Interrupting a Continuous Blast of Air, Designed Especially for Artificial Respiration," by R. A. Gesell and J. Erlanger.

"A Simple Liver Plethysmograph," by C. W. Edmunds.

"An Artificial Circulation Apparatus for Students," by W. P. Lombard.

"A Simplified and Inexpensive Oxidase Apparatus," by H. H. Bunzel.

"An Improved Form of Apparatus for Perfusion of the Excised Mammalian Heart," by M. Dressbach.

Business Meetings

Executive sessions were held by the Pharmacological Society on Monday, December 29, at 5 P.M. and on Tuesday, December 31, at 12:30 P.M. The following officers were elected for the year 1914:

President—Dr. Torald Sollmann.

Secretary—Dr. John Auer.

Treasurer—Dr. William deB. MacNider.

Additional members of the council—Dr. John J. Abel, Dr. A. L. Loevenhart.

Membership committee—Dr. Reid Hunt (term expires 1916).

Election of New Members.—The names of the following candidates were sent to the council by the membership committee, recommended for election by the council and elected by the society: Dr. A. E. Cohn, Rockefeller Institute, New York City; Dr. H. F. Helmholtz, Sprague Memorial Institute, Chicago, Ill.; Dr. W. A. Jacobs, Rockefeller Institute, New York City; Dr. Hugh MacGugan, Northwestern Medical School, Chicago, Ill.

Federation News.—A detailed statement of the developmental effect which this first meeting of the three societies has exerted upon the federation formed at present by these societies, will be given by the general secretary of the federation for the year 1913, Dr. A. J. Carlson. Only one action, that of the Pharmacological Society, need be reported here. It will be remembered that delegates from the Physiological, Biochemical and Pharmacological societies met in Cleveland last year (1912) to establish a federation of the American societies for experimental biology. Among the motions passed unanimously was one which provided for the shifting of papers, with the author's consent, from the program of one society to that of another, if it were considered advisable by the secretaries. In order to prevent a possible conflict with the spirit of Section 2, Article III, of the constitution of the Pharmacological Society, which states that no one shall be admitted to membership who is in the permanent employ of any drug firm, a motion was put and carried unanimously by the Pharmacological Society in its executive session, recommending that no paper should be transferred to the program of the Pharmacological Society without the explicit consent of its secretary. This was done in order to prevent as far as possible the appearance of any paper of a commercial nature on the programs of the Pharmacological Society, for the other two members of the federation do not have this clause which excludes from membership those in the employ of business concerns. It may be stated that the Pharmacological Society did not take this action because of any specific occurrence, but because the society deemed it proper at this time to again emphasize its individual position in the matter.

Dinners and Smokers.—Excellent subscription dinners of very moderate cost formed an enjoyable feature of the Philadelphia meetings and were at-

tended not only by the members of the federation, but also by the Naturalists, Zoologists and Pathologists. They were held on the evenings of December 29 and 30 at the Walton Hotel and Kugler's restaurant, respectively. There were only a few speeches; at the first dinner Drs. W. W. Keen and S. J. Meltzer spoke; at the second dinner the Naturalists presided and Dr. Raymond Pearl delivered a short address.

At the last executive session of the society a motion was passed unanimously to thank the local committee representing the University of Pennsylvania and Jefferson Medical College for the comprehensive and efficient way with which all arrangements for the meetings and the visitors' comfort were made. No names are mentioned in this expression of appreciation because the secretary is informed that practically every Philadelphia member of the three constituent societies labored on the local committee to make the first meeting of the federation as enjoyable as possible. It will be the opinion of every one present that their efforts were entirely successful, that the visitors attended with pleasure and left with regret.

JOHN AUER,
Secretary

THE ROCKEFELLER INSTITUTE

SOCIETIES AND ACADEMIES

THE ANTHROPOLOGICAL SOCIETY OF WASHINGTON

At a special meeting of the Society held on November 4, at the National Museum, Dr. John R. Swanton read a paper entitled, "The Indian Village." He stated that while it is a common notion that country life preceded urban life, this view is not absolutely correct, urban life in its germs going back almost as far as man himself. He then took up the various factors tending to produce the village, determine its character, and subsequently knit it together. These he found to be of three orders, material, social and religious. Among the first he enumerated material available for the construction of houses, position with reference to the food supply and fresh water, and occasionally also position with reference to the sun. Among social factors he treated trade, desire for exchange of ideas, need of mutual protection and relationship, especially in the peculiar form it assumed under totemism. Finally the growth of a village or town cult was traced from the practical independence of shamanism pure and simple to the complete town ritual, sometimes directly, sometimes through the fusion of clan ceremonies

and sometimes through the rituals of religious or other societies. These factors were illustrated by reference to the tribes of the North Pacific Coast and the Gulf area. A possible evolution was suggested in three stages, first, the haphazard collection of hunters, fishers, or perhaps agriculturalists, in a certain spot; second, the development of social relations among them, particularly through intermarriage, and thirdly, a religious seal or stamp of unity, though it was not the writer's intention to set this up as a hard and fast process of evolution. It was noted that totemic clans among some tribes might have been evolved in a similar manner. In conclusion, a short comparison was made between the Indian village and the modern city, attention being called to the fact that in the latter the most important determining factor is trade, while in the former relationship, religious observances, and to some extent motives of protection, were much more prominent.

The subject was discussed at some length by Mr. J. N. B. Hewitt, who confined his remarks to the village in the social organization of the Iroquois. The basis of the social organization was actual or fictitious blood kinship traced through the mother. The cohesiveness of the several units was obtained through the ties of duty and privilege subsisting between clans united by the marriage of their sons and daughters. The clans were organized into two phratries or sisterhoods of clans, one of which represented the masculine and the other the feminine, in nature. This division was maintained in all public meetings. The one side was, therefore, called the "father side," and the other, the "child side," which of course was the "mother side." Strong lines of actual or artificial kinship and cleavage existed between these two groups.

The clans' totems have no especial religious significance at present, that is, there are no ceremonies in honor of them. That there were such in early times is quite possible. The decadence of the worship of the clan totem was probably due to the unification of the clan government into that of the tribe, and later, of the tribe into that of the confederation. The great influence of the council of women, composed of mothers only, in the affairs of the village and tribe and confederation was emphasized, and illustrated by the effectiveness with which they could stop or prevent a war. They needed only to forbid their sons to engage in warlike activity under penalty

of becoming outlaws to the tribe and confederation. The gradual adoption of the Tuscarora tribe of North Carolina by the Iroquois League on motion of the Oneidas as their sponsors, was described, the Tuscaroras being first regarded as infants, then as boys who were not allowed to take part in the wars and councils of the League, and then, finally, as warriors having their own federal chiefs to represent them in the Federal Council of the League.

The 469th regular meeting of the society was held November 25, 1913, the president, Mr. Stetson, in the chair.

Dr. Daniel Folkmar, who has charge of the report on "Mother Tongue" in the Bureau of the Census, addressed the Society on "Some Results of the First Census of European Races in the United States." Statistics of the mother tongue, or native language, of the "foreign white stock" of the United States are presented in the report soon to be issued by the Bureau of the Census. It was prepared under the supervision of the chief statistician for population, assisted by the speaker as expert special agent. There are presented, for the first time in the census, figures directly relating to the ethnic composition of the white population of the United States, in so far as that is indicated by the native language. This term is taken to mean the language of customary speech in the homes of the immigrants before immigration.

One of the most interesting facts disclosed in this report is the great numerical preponderance which is still held by the mother tongues of northwestern Europe, as a whole, notwithstanding the high rank numerically which has been gained by a few individual mother tongues from eastern and southern Europe—especially the Italian, Polish and Yiddish. These three now stand third, fourth and fifth in rank. The English and Celtic mother tongues are by all odds the ones most largely represented in the foreign white stock of the United States. The number, 10,037,420, is considerably greater than that of the German mother tongue, which latter contributes more than one fourth (27.3 per cent.) of the total foreign white stock of the United States, as reported in 1910. Italian, Polish and Yiddish come next in rank, but none of them number as much as one fourth of the German. To these three mother tongues, intermediate in rank but considerable in numbers, may be added the Swedish, French and Norwegian, all belonging to northwestern Europe, except a por-

tion of the French. No other mother tongue than the eight thus far enumerated furnishes as much as 2 per cent. of the total of the foreign white stock of the United States, or numbers as much as 1,000,000. The eight major mother-tongue stocks already named account for 87.5 per cent. of the total foreign white stock.

How small a factor the "new" immigration from southern and eastern Europe really is up to the present time, may be better shown by comparing it with the total white population of the United States. Taking as 100 per cent. the total white population of the United States in 1910, numbering 81,731,957, the so-called "native stock" constitutes 60.5 per cent. and the three great linguistic families of foreign stock from northwestern Europe constitute 27.1 per cent., making a total of 87.6 per cent. The elements from southern and eastern Europe constitute, therefore, less than 13 per cent. of the total. Of this the two principal Latin mother tongues—the French and the Italian—contribute less than 5 per cent., and the two principal Slavic mother tongues—the Polish and the Bohemian—and the Hebrew, taken together, contribute also less than 5 per cent., leaving to all the remaining mother tongues another 5 per cent. or less of the total. Of the total foreign white stock of the United States, 32,243,382, there are 8,817,271 persons who are of German stock when counted according to mother tongue, but a trifle under 8,500,000 (8,495,142) of German stock when counted by their country of origin, Germany.

Immigrants from Austria are far more Slavic than Germanic. Russian immigration is shown to be far more Hebrew (52.3 per cent.) than Russian (2.5 per cent.) or even Slavic. Immigration from Turkey in Europe is not so much Turkish as Greek and Bulgarian. Both the first and the second generations of immigration from Russia show that over 50 per cent. report Yiddish and Hebrew as their mother tongue. The returns for "Yiddish and Hebrew" reflect ethnic composition less satisfactorily than the returns for other mother tongues; A part—how large a part there is no means of judging—of those whose ancestral language is Hebrew doubtless have reported German, English, Polish or other mother tongues. Of the total number of Yiddish-speaking people 838,193 came from Russia, 144,484 from Austria-Hungary, 41,342 from Roumania, 14,409 from the United Kingdom, and 7,910 from Germany.

The full list of mother tongues as reported at

the Thirteenth Census is given for the total foreign white stock (which includes the foreign born and the natives of foreign or mixed parentage) and for the foreign-born whites separately, as follows:

Mother Tongue	Total Foreign White Stock, 1910	Foreign born White
All mother tongues	32,243,382	13,345,545
English and Celtic	10,037,420	3,363,792
Germanic:		
German	8,817,271	2,759,032

SCIENCE AND EDUCATION

A series of volumes for the promotion of scientific research and educational progress

Edited by J. McKEEN CATTELL

Volume I. The Foundations of Science. Including Science and Hypothesis; The Value of Science; Science and Method, by H. POINCARÉ

Authorized English translation by Professor George Bruce Halsted with a preface by the author and an introduction by Professor Josiah Royce. *Published December, 1913. Pages xii+553. Price, \$3.50 net.*

Volume II. Medical Research and Education

By RICHARD M. PEARCE, The University of Pennsylvania; WILLIAM H. WELCH, W. H. HOWELL, FRANKLIN P. MALL, LEWELLYS F. BARKER, The Johns Hopkins University; CHARLES S. MINOT, W. B. CANNON, W. T. COUNCILMAN, THEOBALD SMITH, Harvard University; G. N. STEWART, Western Reserve University; C. M. JACKSON, E. P. LYON, University of Minnesota; JAMES B. HERRICK, Rush Medical College; JOHN M. DODSON, University of Chicago; C. R. BARDEEN, University of Wisconsin; W. OPHÜLS, Stanford University; S. J. MELTZER, Rockefeller Institute for Medical Research; JAMES EWING, Cornell University Medical College; W. W. KEEN, Jefferson Medical College; HENRY H. DONALDSON, Wistar Institute of Anatomy; The late CHARLES A. HERTER, Columbia University; The late HENRY P. BOWDITCH, Harvard University.

Published October, 1913. Pages vi+536. Price, \$3.00 net.

Volume III. University Control

By J. McKEEN CATTELL. Together with a series of Two Hundred and Ninety-nine Unsigned Letters by Leading Men of Science holding Academic Positions and Articles by JOSEPH JASTROW, GEORGE T. LADD, JOHN J. STEVENSON, J. E. CREIGHTON, J. McKEEN CATTELL, GEORGE M. STRATTON, STEWART PATON, JOHN JAY CHAPMAN, JAMES P. MUNROE and JACOB GOULD SCHURMAN.

Published March, 1913. Pages x+484. Price, \$3.00 net.

SINGLE COPIES, 15 CTS.
ANNUAL SUBSCRIPTION, \$5.00

Drew's Invertebrate Zoology

Just Issued—New (2d) Edition

For this edition Professor Drew has subjected his book to a very searching revision, bringing it into accord with the latest knowledge. His work gives you a working knowledge of comparative anatomy and an appreciation of the adaptation of animals to their environments.

Prof. John M. Tyler, Amherst College: "It covers the ground well, is clear and very compact. The table of definitions is excellent."

Invertebrate Zoology. By Gillman A. Drew; Ph.D., Assistant Director of the Marine Biological Laboratory, Woods Hole, Mass. 12mo of 213 pages. Cloth, \$1.25 net.

Daugherty's Economic Zoology

This work is issued, for convenience, in two parts. Part I is a *Field and Laboratory Guide*, interleaved for notes. Part II is the textbook part or the *Principles*. The *life and habits* are emphasized.

J. Remsen Bishop, Ph.D., Eastern High School, Detroit. "The illustrations alone prove the book superior to any other."

By L. S. Daugherty, M.S., Ph.D., Professor of Science, Missouri Wesleyan College; and M. C. Daugherty. Part I—*Field and Laboratory Guide*. 12mo of 275 pages, interleaved. Cloth, 1.25 net. Part II—*Principles*. 12mo of 406 pages, illustrated. Cloth \$2.50 net.

McFarland's Biology

This work has chapters on the origin of life and its manifestations, the cell and cell division, reproduction, ontogenesis, conformity to type, divergence, structural and blood relationship, parasitism, mutilation and regeneration, grafting, senescence, etc.

Prof. W. R. McConnell, Pennsylvania State College: "It has some admirable features, the most valuable of which is the careful resume of the subjects of heredity and evolution."

Biology: General and Medical. By Joseph McFarland, M.D., Professor of Pathology and Bacteriology, Medico-Chirurgical College, Philadelphia. 12mo of 440 pages, illustrated. Cloth, \$1.75 net.

Stiles' Nutritional Physiology

Dr. Stiles takes up each organ, each secretion concerned with the process of digestion, discussing the part each plays in the physiology of nutrition. A valuable feature is Dr. Stiles' happy use of homely similes.

Prof. Colin C. Stewart, Dartmouth College: It is remarkable for the fineness of its diction and for its clear presentation of the subject."

Nutritional Physiology. By Percy G. Stiles, Assistant Professor of Physiology in Simmons College, Boston. 12mo of 271 pages, illustrated. Cloth, \$1.25 net.

W. B. SAUNDERS COMPANY, W. Washington Sq., Phila.

Scientific Journals of The Cambridge University Press

We have assumed the American agency for these journals. Requests for information and subscriptions should be sent to the address given below.

BIOMETRIKA. Edited by Karl Pearson. Subscription price, \$7.50 a volume; single copies, \$2.50.

A journal for the statistical study of biological problems. *Biometrika* appears about four times a year. A volume containing about 500 pages, with plates and tables, is issued annually.

JOURNAL OF GENETICS. Edited by W. Bateson and R. C. Punnett. Subscription price, \$7.50 a volume; single copies, \$2.50.

A periodical for original research in heredity, variation, and allied subjects. It contains articles summarizing the existing state of knowledge in various branches of genetics. Adequate illustration is provided, and, where the subject-matter demands it, free use is made of colored plates.

THE JOURNAL OF HYGIENE. Edited by G. H. F. Nuttall. Subscription price, \$5.25 a volume; single copies, \$1.75.

The Journal is devoted to the scientific investigation of the causes of health and disease. It is issued as material accumulates. A volume containing about 500 pages, with plates and figures, is issued annually.

PARASITOLOGY. Edited by G. H. F. Nuttall and A. E. Shipley. Subscription price, \$7.50 a volume; single copies, \$2.50.

Parasitology fulfills the purpose of encouraging the study of parasitology, especially in relation to disease, by providing a means for the publication of papers relating to pathogenic and disease-transmitting parasites. The Journal is an outgrowth of *The Journal of Hygiene*. It is published about four times a year. Subscribers to the *Journal of Hygiene* may become subscribers to *Parasitology* at the reduced rate of \$5.25 per volume.

THE MODERN LANGUAGE REVIEW. Edited by J. G. Robertson, G. C. Macaulay, and H. Oelsner. Subscription price, \$3.00 a volume; single copies, \$1.00.

The *Modern Language Review* is the only periodical published in Great Britain which is especially devoted to scholarship and research in mediaeval and modern languages and literatures. Attention is also called to the fact that the English language and literature are receiving a very large share of space in the Journal.

THE BRITISH JOURNAL OF PSYCHOLOGY. Edited by C. S. Myers. Subscription price, \$3.75 a volume.

Devoted exclusively to psychology in all its branches, analytical, genetic, comparative, experimental, pathological, individual, ethnical, etc. Besides original articles, the Journal contains from time to time critical discussions of current controversial topics. Monograph supplements are also issued and sold separately.

THE JOURNAL OF AGRICULTURAL SCIENCE. Edited by Professor R. H. Biffen, A. D. Hall, and Professor T. B. Wood. Subscription price, \$3.75 a volume; single copies, \$1.25.

The Journal is intended for agricultural teachers and experts, farmers, and land agents having an interest in the scientific side of their profession, agricultural analysts, seedsmen, millers, manure manufacturers, etc.

THE BIOCHEMICAL JOURNAL. Edited for the Biochemical Society by W. M. Bayliss and Arthur Harden. Subscription price, \$5.25 a volume.

The Journal will be of service to those biologists and chemists who are interested in the investigation of problems common to both, such as the chemical problems connected with agriculture, brewing, animal and vegetable physiology and pathology, etc. The Journal is issued every two months.

THE JOURNAL OF ECOLOGY. Edited for the British Ecological Society by Frank Cavers. Subscription price, \$3.75 a volume; single copies, \$1.25.

The *Journal of Ecology* aims to present a record of and commentary upon the progress of ecology, considered in its widest sense, throughout the world, including in its scope not only work dealing with general principles, methods, surveys, and other ecological studies, but also publications in geography, geology, meteorology, climatology, physiology and anatomy, the science of soils, and other branches of natural science so far as these have a direct bearing upon ecology.

Note—Prices on back volumes vary, and postage from London is charged on back volumes and single copies. Quotations to include postage rendered on request.

DR. SMITH is a practitioner in one of the large cities of the middle West. He is a man of good training, a classical graduate, took his professional course in one of our best schools, and did hospital service both at home and abroad. He is a general practitioner and keeps well posted in all that he does. He makes no claim to universal knowledge or skill, but is conscientious in all his work, and when he meets with a case needing the service of a specialist he does not hesitate to call in the best help. He has made a good living, demands fair fees from those who are able to pay, and gives much gratuitous service to the poor. He is beloved by his patients, held in high esteem by his confreres, and respected by all who know him. He is a keen observer, reads character for the most part correctly, and is not easily imposed upon. While he recognizes the value of his services, he is not in the practise of medicine with the expectation of getting rich, and his interests are largely humane and scientific. He has deep sympathy for those whose ignorance leads them to sin against their own bodies, but he is devoid of weak sentimentality and does not hesitate to admonish and even denounce the misdeeds of his patients whatever their social position. During twenty years of practise in the same locality he has become acquainted with the vices and virtues of many families. He is not looking for the coming of the millenium, but he is often impatient of the slow pace with which the race moves

¹ MSS. intended for publication and books, etc., intended for review should be sent to Professor J. McKeen Cattell, Garrison-Hudson, N. Y.

¹ Read at the seventh annual meeting of the Association of Presidents of Life Insurance Companies, December 11, 1913.

towards physical, mental and moral betterment. One of his patients is a large manufacturer employing many unskilled laborers. Dr. Smith has often pointed out to this man that the efficiency of his working force would be multiplied many times were the men paid better wages, the work done in rooms better lighted and ventilated, and in general with a little more humaneness shown them. Another is at the head of a large mercantile house which employs clerks at the lowest possible wages and makes the conditions of life well nigh unendurable. A wealthy woman gives largely to church and charity from her revenues which come from the rental of houses in the red light district. Another of the doctor's patrons is a grocer who sells "egg substitutes" and similar products "all guaranteed under the pure food law." We will not continue the list of the doctor's patrons and it must not be inferred that all are bad, for this is not true. The majority are honest, conscientious people, as is the case in all communities. Our country has a population of nearly one hundred millions. Millions of these are decent, respectable citizens, not altogether wise, but for the most part well intentioned. Thousands are brutal in their instincts, criminal in their pursuits, and breeders of their kind. We claim to be civilized, but there are those among us who would be stoned to death were they to attempt to live in a tribe of savages. But I must stop these parenthetical excursions and get back to Dr. Smith and his dream. On a certain day in November of the present year he had been unusually busy, even for one whose working hours frequently double the legal limit. During his office hours he had seen several cases which gave him grave concern. There was William Thompson, the son of his old classmate and college chum, now Judge Thompson. William finished at the old

university and is now an embryo lawyer promising to follow in the footsteps of his honored and honorable father, but William belonged to a fast fraternity at college and came to Dr. Smith this morning with copper-colored spots over his body and a local sore. The doctor easily diagnosed the case and pointed out to William that he was a walking culture flask of spirochetes, a constant source of danger to all who should come in contact with him, and that years of treatment would be necessary to render him sound again. On the lip of a girl, the daughter of another old friend, the doctor had found a chancre caused by a kiss from her fiancé, a supposedly upright man prominent in church and social circles. He had seen a case of gonorrhea in a girl baby contracted from her mother, the wife of a laboring man. A case of gonorrheal ophthalmia in a young man whose only sin was that he had used the same towel used by an older brother next demanded his attention. Several cases of advanced tuberculosis among those who had been told by less conscientious physicians that the cough was only a bronchial trouble made Dr. Smith lament the standard of skill and honor among some of his professional brethren. Rapid loss in weight in an old friend who had been too busy to consult him earlier was diagnosed as neglected diabetes. In another instance dimness of vision and frequent headaches persisting for months had not sufficed to send an active business man to the physician. This proved to be an advanced case of Bright's disease, which should have been recognized two years earlier. Urinary, ophthalmoscopic and blood pressure tests demonstrated the seriousness of the present condition. A breast tumor on the wife of an old and respected friend showed extensive involvement of the axillary glands and the operation demanded promised only temporary relief, while

had it been done months before, complete removal of the diseased tissue would have resulted. In making his calls for the day Dr. Smith had experienced both among the well-to-do and the poor many things which had brought within the range of his vision more and darker clouds than those which floated in the dull November sky. More than a year before he had become estranged from the family of one of his oldest and best friends. The breaking of this relationship which had continued from his earliest professional service and had been filled with the common joys and sorrows shared only by the family physician and those under his charge, had cast a deep shadow over the doctor's life. He had officiated at the birth of each of his friend's five children, and he felt a parental love and pride in them as he saw them grow into healthy womanhood and manhood. A little more than a year ago, he learned that the eldest of these children, a beautiful and healthy girl of eighteen, was engaged to a young man whom he knew to be a rake. In a spirit of altruism he had gone to the father and mother and protested against the sacrifice of the daughter. This kindly intended intervention was met with a stormy rebuff, and the doctor was rudely dismissed from his friend's house. But when the young woman whose life with her unfaithful husband had made her deeply regret her fatal infatuation, felt the first pains of childbirth she begged of her parents that her old friend might be sent for, and that morning he had delivered her of a syphilitic child. How unlike the previous births at which he had officiated in this friend's house! It had been the custom to have the doctor at every birthday dinner given the five children, and one of the boys bore his name. There would be no birthdays for this, the first grandchild, and what could the future promise the young mother? Surely,

the November day was overcast with clouds for Dr. Smith before its gray light awoke the slumbering city. As he walked the few short blocks from his friend's to his own home, he cried in deepest sorrow how many thousands of daughters must be sacrificed before their parents will permit them to walk in the light of knowledge and not in the shadow of ignorance. After a breakfast, which was scarcely tasted, he read in the morning paper that the announcement that "Damaged Goods" was to be given in his University town had met with such a storm of protest from the learned members of the faculty that the engagement had been cancelled. "Surely," he said, "the fetters of prudery and custom bind both the learned and the unlearned."

After his morning office hours Dr. Smith visited his patients at the city hospital. Here is a wreck from cocaine intoxication, the poison having been purchased from a drug-store owned by a prominent local politician. In a padded cell is a man with delirium tremens, a patron of a gilded saloon run by another political boss. In the lying-in ward are a dozen girls seduced in as many dance halls with drinking alcoves. Time will relieve these girls of the products of conception, a longer time will be required to free them from the diseases which they have contracted, but all time will not wash away the stains on their lives, and what of the fatherless children to be born? Thirty beds are filled with typhoids, who under the best conditions must spend long weeks in the bondage of a fever, which day by day gradually but inexorably tightens its grasp. The furred tongues, glazed eyes, flushed cheeks, bounding pulses, emaciated frames, delirious brains were all due to the fact that a large manufacturer had run a private sewer into the river above the water works. The greed and ignorance of one business firm had

been permitted to endanger the lives of half a million of people. In his family calls the doctor met with conditions equally lamentable. A fond mother in her ignorance had nursed a sore throat in one of her children with domestic remedies. The membranous patches on the tonsils, extending upward into the nasal passages and downward into the larynx, and the cyanotic face with labored breathing showed that even the magical curative action of diphtheria antitoxin, that wonderful discovery of modern medicine, would be of little avail in this individual case. The other children were treated with immunizing doses and the doctor had the consolation of knowing that death's harvest in that household would be limited to the one whom the mother's ignorance had doomed.

The next call brought Dr. Smith to a home in which the conditions were equally deplorable and still more inexcusable. One of the children some months before had been bitten by a strange cur which soon disappeared in the alley. The wound was only a scratch and was soon forgotten. Now, the child was showing the first symptoms of that horrible disease hydrophobia. But dogs must not be muzzled. Women with plumes, torn from living birds, in their hats, formed a society for the prevention of cruelty to animals, and so declared.

It must not be inferred that all of Dr. Smith's experiences on that November day were sad. Men are mortal; all sickness is not preventable, accidents will happen and distressing injuries result. This world is not an Eden and no one expects that all sorrow will be banished from it. Decay and death approach with advancing years. Strength and weakness are relative terms and those possessed of the former must help bear the burdens of those afflicted with the latter. Dr. Smith being a hard-headed, reasonable, scientific man, is no Utopian,

and he frequently meets in sick rooms experiences which greatly increase both his interest and his confidence in man. He finds the young and vigorous denying themselves many pleasures in order to brighten the pathways of the old and infirm, the fortunate lending a helping hand to the unfortunate, and the wise leading the unwise. No one, more than the family physician, can measure and appreciate the innate goodness that springs without an effort from the heart of humanity. It is difficult for the physician of large experience to unreservedly condemn any one, and he is inclined to regard all sins as due to either heredity or environment. However, it must be admitted that on this day Dr. Smith had seen but little sunshine and the clouds that had gathered about him had hidden the virtues and magnified the vices of his community, and especially was this true of the vice of ignorance, for ignorance which results in injury to one's fellows is not only a vice but a crime, a moral, if not a statutory one.

Late that night as the doctor sat before his grate he fell asleep, and now he is busy among his patients in a way hitherto quite unknown to him. His waiting-room is filled with people, old and young, of both sexes, who have come to be examined in order to ascertain the exact condition of their health. A young man before proposing marriage to the woman of his choice wishes a thorough examination. He wishes to know that in offering himself he is not bringing to the woman any harm. He desires to become the father of healthy children and he is not willing to transmit any serious defect to them. He tells the doctor to examine him as carefully as he would were he applying for a large life insurance. The doctor goes through the most thorough physical examination and tests the secretions and blood with the utmost care. He

understands his own responsibility in the matter and appreciates the high sense of honor displayed by his patient. A young woman for like reasons has delayed her final answer to the man who has asked her hand in order that the doctor might pass upon her case. Here is the doctor's old friend, William Stone. Mr. Stone is in the early fifties. He has been a highly successful, honorable business man, has accumulated a sufficiency and enjoys the good things which his wife prepares for the table. A careful examination of the urine leads the doctor to caution Mr. Stone to reduce the carbohydrates in his food. Mr. Perkins, a lawyer who throws his whole strength in every case he tries, and of late has found himself easily irritated, shows increased urinary secretion and a blood pressure rather high. A vacation with light exercise and more rest is the preventive prescription which he receives. Mrs. Williams, after being examined by Dr. Smith, undergoes a slight operation under local anesthesia, and is relieved of the first and only malignant cells found in her breast. Richard Roe, who is preparing for a long journey, is vaccinated against typhoid fever, a disease no longer existent in Dr. Smith's city since pollution of the water has been discontinued. John Doe, who is a mineralogical expert and wishes to do some prospecting in high altitudes, has his heart examined. There are numerous applicants for pulmonary examination. This is done by Dr. Smith and his assistants in a most thorough and up-to-date manner, and advice is given each according to the findings. It has been many years since Dr. Smith has seen an advanced case of pulmonary tuberculosis and the great white plague will soon be a thing of the past. Every body goes to a physician twice a year and undergoes a thorough examination. The result of this examination is stated in

a permanent record and no two consecutive examinations are made by the same physician, in order that a condition overlooked by one may be detected by another. Cases of doubt or in which there is difference of opinion are referred to special boards. The average of human life has been greatly increased and the sum of human suffering has been greatly decreased. Preventive has largely replaced curative medicine. Tenements are no longer known; prostitution and, with it, the venereal diseases have disappeared; institutions for the feeble-minded are no longer needed, because the breed has died out; insanity is rapidly decreasing because its chief progenitors, alcoholism and syphilis, have been suppressed. These and many other pleasing visions come to Dr. Smith in his dream, from which he is startled by the ring of the telephone at his elbow. The call says: "Come quickly to Pat Ryan's saloon at the corner of Myrtle and Second. There has been a drunken row. Bring your surgical instruments." Then the smiles which had played over the face of the doctor in his dream were displaced by lines of care and he went forth into the darkness of ignorance and crime.

There are many Dr. Smiths and they have been seeing pleasing visions in their dreams and meeting with stern realities in their waking hours. Nearly fifty thousand Dr. Smiths constitute the American Medical Association which is expending thousands of dollars annually in trying to so educate the people that unnecessary disease will be prevented. The doctors are asking that the work of the national, state, municipal and rural health organizations may be made more effective, that the knowledge gained in the study of the causation of disease may be utilized. The world has seen what has been done in Havana and on the Canal Zone, how yellow fever and malaria

have been suppressed, and how the most pestilential spots on earth may be converted into healthful habitations for man. Scientific medicine has made these demonstrations and the world applauds, but seems slow to make general application of the rules of hygiene.

Dr. Foster had experienced the doctor's dream when he said to you in 1909:

I look forward with confidence to the time when preventable diseases will be prevented, and when curable diseases will be recognized in the curable stage and will be cured, and I believe the grandest triumphs of civilization will be the achievements which will result from a realization of the possibilities of preventive medicine.

Professor Fischer, a most earnest and intelligent student of the prevention of sickness and the deferring of death has stated that "by the intelligent application of our present knowledge, the average span of human life may be increased full fifteen years."

It has been proposed that the life insurance companies represented here seek to prolong the lives of their policyholders by offering them free medical reexamination at stated intervals. It has been shown that in all probability this would financially benefit the companies in the increased longevity of their policyholders and the increased number of premiums they would pay. This is a business proposition, and I hope that the companies will inaugurate it and thus demonstrate that the lessening of sickness and the deferring of death will pay. Let the insurance men join the doctors and help in the great work for the uplift of the race through the eradication of unnecessary disease and premature death. In this way we can hasten the coming of the better man by making the doctor's dream a reality. I am confident that you will do this, not because it will

pay, but because it is the highest service you can render humanity.

VICTOR C. VAUGHAN

UNIVERSITY OF MICHIGAN

*THE AMERICAN ASSOCIATION FOR THE
ADVANCEMENT OF SCIENCE
SCIENCE, EDUCATION AND DEMOCRACY¹*

SCIENCE, education and democracy—the three great enterprises of the modern world—are in no institution more completely represented than in this American Association for the Advancement of Science and in its section of education. We are organized to advance science in all its range from the most esoteric deduction of the mathematician to the most homely contrivance of the inventor, and at the same time to diffuse scientific knowledge and scientific method among all who are willing to listen. Our membership includes the ablest scientific leaders and equally those who in Bishop Berkeley's phrase are "undebauched by learning." We migrate from place to place for our meetings in order that we may teach and learn in all parts of the country. We form more nearly a democracy of science than any other organization. Education is amalgamated with every section of our association, which is as completely an educational institution as is a university. And as the university, devoted throughout to education, yet may include a department or school of education, so we have conducted in recent years a section of education. This section is concerned with the place of the sciences in our educational system and with improving the methods of teaching them. It has also as its object, perhaps its principal object, the development of a science of education; for there is no other applied science—not agri-

¹Address of the vice-president and chairman of the Section of Education of the American Association for the Advancement of Science, read at Atlanta, Ga., on December 31, 1913.

culture, nor engineering, nor medicine—of equal importance. It is also true that none is more backward and empiric, none in greater need of scientific principles and scientific methods.

The adequacy of much of our mathematical teaching is illustrated by the high-school boy's answer to the question "What follows when the three sides of a triangle are equal?", this being "The other side will be equal too." However that may be, science, education and democracy are the essential sides of the triangular base on which rests the pyramid of the civilization that we have, on which will stand even more solidly the better civilization that is to be. The foundations we can follow downward as far as we may fancy—to prehistoric and prehuman times, to metazoa and protozoa which learn by experience and have a certain equality of opportunity. In the long course of evolution, science and education always have been interrelated. Accumulated and transmitted knowledge has been the basis of education, and in turn education has made possible the accumulation and transmission of knowledge. Thus have come language and writing, the alphabet and printing, tools and machines, fire and shelter and clothing, the cultivation of plants and animals, fine arts and religions, sciences and their applications, codes of conduct and methods to enforce them.

During the historic period there has been a conflict between science and education, on the one side, and democracy, on the other. Among the lower animals and to a certain extent in savage tribes, there exists a kind of democracy and equality of opportunity. Each individual faces the world with the endowment received at birth, not greatly helped by the position of his family or his group. But when knowledge and education became so complicated that they could not be shared equally by all, when

wants increased to the extent that some had to be deprived in order that others might be gratified, when there was competition for property and wealth, then society was thrown into a patriarchal or feudal or despotic or oligarchic system. The material resources did not suffice to provide adequately for all; the stronger seized on them, and the many were compelled to toil in ignorance and poverty in order that the few might enjoy knowledge, leisure and luxury. Unto those who had was given and from those who had not was taken even that which they had. The system of individual, family, class, race and sex privilege gained the saddle and still rides us all.

The dominance of privilege was perhaps a necessary stage in social development. It may be that power and wealth concentrated in individuals, citizens and slaves, an aristocracy exploiting serfs, dependent women, subject races, were required to save the primitive state from submergence under savagery and barbarism, to develop its institutions, to promote science and the arts, to set standards of conduct. Plato provided slaves for his republic; the New Testament accepted Caesar, slavery and the subjugation of women. When the resources of society were sufficient to provide adequately for only a part of its members, universal education and equality of opportunity could not exist. The masses were compelled to work incessantly for the bare necessities of life, in order that there might be classes in a position to advance science and the arts. When the average age at death was twenty years, the race could only be continued if women spent their lives in bearing, rearing and burying their children.

But science with its applications has recreated the world. Within a century, or at most two centuries, it has quadrupled the efficiency of labor and doubled the length of life. Steam and electricity enable one

man to do what formerly required a hundred. A needle or a lucifer match is worth a thousand times what it costs. The mail which I send and receive daily at an expense of two or three dollars would cost hundreds of thousands of dollars if each piece were delivered separately without modern methods of transportation. It would take all the time of all the people in the United States to write part of what they now print. In the western world famine is no longer a factor. Cholera, smallpox and the plague have decreased their toll to less than one per cent. of what they once claimed. Infant mortality has been reduced from forty to ten in a hundred. The average life of a woman after the birth of her last child is perhaps three times what it was.

The economy of labor and of life which the applications of science have wrought has abolished the need of productive toil by children and has made possible their universal education. The wealth of society is now sufficient to support adequately every child, to give it the education that opens the gateway to the career for which it is fit, to provide equality of opportunity and a true social democracy. At the same time this education, which can be continued through life, for not more than four hours a day of routine labor by each adult would suffice to provide its necessities, gives the basis for a stable and complete political democracy. The exploitation of children, sex slavery, industrial servitude, kleptocratic classes, have become wanton and intolerable. It is also true that in addition to its economic control, science has been a dominant factor in education and in life. It not only makes the education of all possible, but its subject matter and especially its methods supply the best material for education. It gives us leisure and at the same time means to use leisure

worthily. It has lessened ignorance, superstition and unreason; it has taught us to tell the truth as we see it, and in increasing measure to see the truth as it is.

Material science has provided the economic foundations of democracy. I believe that the science of conduct justifies democracy and will guide its laws and institutions. But this, it must be acknowledged, is only a matter of opinion. One of my college friends has become perhaps the most distinguished mathematical physicist of the world. Standing for parliament recently, the four principal theses of his electoral address were: Maintenance of a hereditary house of lords, introduction of a protective tariff, the denial of home rule to Ireland, state schools under the church. These reactionary policies were endorsed by his election to represent one of the great English universities. So little do intelligence, character and scientific attainment lead to agreement in regard to social and political theories. Each of us is enmeshed in the net of his class, and has but little freedom of movement. The individual does not as a rule act in the light of reason, but by instinct and impulse, and it is well that he does, for they are the safer guides. But while individual conduct is in the main automatic response to chance circumstance, it is possible by forethought to select individuals and to arrange circumstances. Education and scientific research are subject to social control and should be the chief concern of a democratic society.

American democracy has been on the whole favorable to common-school education. It is admitted that our masters must be taught, and in practise this country has led in public elementary education and now leads in the provision of high-school and college education. More than 96 per cent. of all children from ten to fourteen years of age are enrolled in school. There are

one million two hundred thousand students in high schools; a third of a million in higher institutions. Reading and writing have become, like air and water, the common heritage of all. This is the great achievement of democracy in the modern world. Thereby it has assured its own permanence and has opened up the way along which it will advance.

Reading and writing are indeed only pass-keys which unlock various gates. Further progress by way of the newspaper and the moving-picture show is halting. We have inherited the educational ideals of the idling classes and their dependent priests and clerks. The common school prepares for the high school, the high school for the college, the college for "Who's Who." Our scholastic methods, invaluable for intercommunication at a distance in space and time, may inhibit thought and action, even the finer forms of speech and the more direct expression of the emotions. A few days since a neighbor in the country, now over eighty years old, who suffered or enjoyed such educational limitations that she can barely read, wrote to me "I am still alive but i don't know what for." At school she would have been taught to use modestly a capital "I" for the first personal pronoun and not to end a sentence with a preposition. I have learned these things and to use words such as "direct" and "effective," but I do not use words so directly and effectively as my neighbor. One of my children at the age of ten, never having been in school, wrote verses such as:

An army marching through the fields
They had on their shields
They were ready to fight until night
But there was no army to fight

and

The breeze that blows is the salt sea breeze
After instruction in English she relapsed

into the conventional and the commonplace.

Who now can write a sentence such as "In the beginning God created the heaven and the earth," or sentences such as are found on every page of Homer and Dante? In the words of Arnold:

What girl
Now reads in her bosom as clear
As Rebekah read, when she sate
At eve by the palm-shaded well?
Who guards in her breast
As deep, as pellucid a spring
Of feeling, as tranquil, as sure?

What bard,
At the height of his vision, can deem
Of God, of the world, of the soul,
With a plainness as near,
As flashing as Moses felt
When he lay in the night by his flock
On the starlit Arabian waste?
Can rise and obey
The beck of the Spirit like him?

We do not know what well-educated men and women who could not read would be like. If the authors of the Homeric poems could read and write they did not spend much time in such occupations. Certainly they did not learn to use their own language by the study of Latin. A friend asked a porter in a Swiss hotel, who used many languages with equal facility and incorrectness, which was his native tongue. He replied that he did not know, he spoke all languages; then, in answer to the question as to the language in which he thought, "I neva tink."

Children must learn to read, write and calculate, but under proper conditions of family and society schools to teach these tricks would be nearly as superfluous as schools to teach infants to walk and talk. Those familiar with the literature of pedagogic edification will be weary of the iteration that the word "educate" means to lead out, which, not cramming full, should

be the object of our schools. This is not only trite, but also true. Every psychologist knows that perceptions are not there to be perceived, but as a condition of reactions; that we learn by doing; that conduct is the only thing that counts. But it is also true that by its etymology the word "educate" might mean to lead out the individual for the work for which he is fit, to select the "dukes," the leaders, for a democracy. This is the greatest service of education. We learn to do things not by preparing to do them, but by doing them; we get a wider outlook not by so-called cultural studies, but by association with those who have broad and unselfish interests; we must learn what others know, but it is more important to do what we have not been taught and what others have not done. The chief object of the school is to open for each child the gateway to the career for which he is fit. Democracy does not mean equal mediocrity of all, but performance by each in accordance with his ability.

What a man can do is prescribed at birth; what he does depends on opportunity. The famous clause "all men are created equal" was probably intended by Jefferson to mean equal in respect to life, liberty and the pursuit of happiness. However that may be, the doctrine of evolution by natural selection has taught every one that the individuals of a species are unlike at birth. The amount of congenital unlikeness in men and the extent to which it is inherited in successive generations, on the one hand, and the degree to which men can be fitted by education and experience for different performances, on the other hand, are scientific problems on the solution of which depends the future of social and political institutions. If superior ability occurs only or chiefly in certain family lines, if classes, races and the sexes are not only different but subordinated one

to the other by the barriers of an impassable heredity, then an aristocratic society and an oligarchic government are imposed by nature. If each finds of necessity his level and his place by native endowment, then universal education and equality of opportunity are of small significance. If, on the contrary, among five children taken at random from the public schools, one is likely to surpass in ability and character the privileged boy at Groton or St. Paul's; if nine boys out of ten and ten girls out of ten have no chance to show what they are fit to do, then our need is more democracy and better opportunity for the fit.

I have found that of our thousand leading men of science, 134 were born in Massachusetts, 3 in Georgia. For each million of their population, Massachusetts and Connecticut have produced a hundred scientific men of high standing; the states of the southern seaboard but two. Does this disparity measure difference of natural ability or difference of opportunity? The frailties of human nature are responsible for two experiments which, if not executed with scientific precision, have been conducted on a large scale. In this country and in Great Britain, four per cent. of children are illegitimate; in continental cities the percentage is as large as twenty and even forty. It is probable that these children have a physical heredity equal to that of the average child, but their social heritage is inferior, and their performance corresponds with their opportunity. If heredity were predominant there should be among our thousand leading men of science some forty of illegitimate parentage, whereas there are few or none. The mulattoes are by their physical heredity midway between the whites and the negroes, with parentage probably superior to the average in both races. But their social position is that of the negroes, and their per-

formance corresponds with their environment rather than with their heredity. There is not a single mulatto who has done creditable scientific work.

According to unpublished statistics which I have collected, 43 per cent. of our scientific men come from the professional classes who form one thirtieth of the population. Probably one half of them are sons of the one per cent. of the population most favorably situated to produce them. A child must be well born if he is to become a large figure in the world, but there may be tens of thousands of children born with the natural endowments of our productive scientific men who are given no opportunity to develop and use their ability for the benefit of society. A child with the exact constitution of Darwin born in China a hundred years ago would surely not have become Darwin. What chance would he have had in this country, or even in England, if his father had not been a man of wealth? The chief object of our educational system should be to select men and women for the work for which they are most fit. To train them for it is also important, but less so. In England one half of its men of performance have been educated at two universities having together some 6,000 students, nearly all from the dominant classes; one half of its cabinet ministers have come from a few interrelated noble families. It may be that there the object of the universities has been to train the privileged classes, of the trade schools to train artisans. Here the end of our schools is to break down, not preserve, the barriers of birth, to provide opportunity, not privilege.

Our democracy has not failed in its quantitative provision of education, but it has been backward in adjusting this education to its needs. In the elementary school, in the high school, in the conventional col-

lege, to a certain extent in the university with its professional schools, outworn traditions have persisted. The high school and college are in large measure traditional female seminaries of the kind that used to teach "Latin, logic and the use of globes." The colleges of liberal arts when women are excluded tend to unite the amusements and amenities of a county club with the frivolous amateurism and the futile scholasticism of its class-rooms. The schools of medicine and of law have been until recently trade schools of poor grade, proprietary institutions largely conducted for the indirect financial profit of the professors. Endowments are now being provided and standards are being raised, but there is something amiss in a system which does not permit a man to become self-supporting or to engage in his life's work until he is twenty-seven years old. If the cost of a physician's education must be \$10,000, this money should be paid for those most competent to profit from it, not for those only whose parents happen to have so much money.

Nothing could be more undemocratic and anti-social than the plan of endowing—namely, compelling the people to support without the power to control—institutions where the sons of the newly rich may acquire the manners and prejudices of the leisure classes, and at the same time to conduct trade schools in order that there may be cheap skilled labor for exploitation. But the road to democracy may be paved with bad intentions. It is one of the ironies of history that the university endowed by wealthy and pious patrons for the education of the clergy and the upper classes, intended for the support of church and state, should by the nature of knowledge subvert the old orthodoxy and the old social and political system. It is safe to predict

that the trade school will do its share to break down the capitalistic regime.

In the charmingly worded address given by the then professor of jurisprudence and politics at the sesquicentennial exercises of Princeton University, the orator said:

I am much mistaken if the scientific spirit of the age is not doing us a great disservice, working in us a certain great degeneracy. Science has bred in us a spirit of experiment and a contempt for the past. It has made us credulous of quick improvement, hopeful of discovering panaceas, confident of success in every new thing. . . . I should fear nothing better than utter destruction from a revolution conceived and led in the scientific spirit. . . . Can any one wonder, then, that I ask for the old drill, the memory of times gone by, the old schooling in precedent and tradition, the old keeping of faith with the past, as a preparation for leadership in days of social change? . . . I have had sight of the perfect place of learning in my thought . . . calm Science seated there, recluse, ascetic, like a nun, not knowing that the world passes, not caring, if the truth but come in answer to her prayer; and Literature, walking within her open doors, in quiet chambers with men of olden time, storied walls about her, and calm views infinitely sweet; here "magic casements, opening on the foam of perilous seas, in fairy lands forlorn," to which you may withdraw and use your youth for pleasure; . . . its air pure and wholesome with a breath of faith; every eye within it bright in the clear day and quick to look toward heaven for the confirmation of its hope.

Fourteen years later the same speaker, with his ear to the ground, heard better voices:

The great voice of America does not come from seats of learning. It comes in a murmur from the hills and woods and the farms and factories and the mills, rolling on and gaining volume until it comes to us from the homes of common men. Do these murmurs echo in the corridors of universities? I have not heard them. (Speech to Pittsburgh alumni, April 17, 1910.)

It is he who listened to the voice of democracy who has been chosen to be its leader.

While it is proper to protest against the

undemocratic survivals in the universities which we have inherited, the great services which they have rendered and now perform should not be forgotten. From the foundation of the universities of Salerno, Bologna, Paris and Oxford to the establishment of the Johns Hopkins, Stanford and Chicago, the university has been one of the principal factors in the advancement of science and in the progress of civilization. Three fourths of our productive men of science are now supported by universities. It is under the ægis of privilege and patronage that we have passed into the dawn of democracy. Our state universities are now assuming leadership, and should be counted with the public schools of which they are the head as our greatest contribution to educational progress and social welfare. The state university, directly responsive to the utilitarian democracy on which it depends, open to men and women on equal terms, selecting from all the people of the state those most fit for higher education and preparing them directly for their work in life, devoted in equal measure to teaching, research and public service, holds high the standard under which we move forward into the newer world.

There is a critical point in intelligence at which it is understood that education and productive science are the investments that pay the highest interest. This nation, thanks to the advances of science and to its natural resources, has the means to educate every child in the manner and to the extent that is desirable for the individual and for society. It has the wealth to make investments in scientific research to the extent that men can be found to carry on the work. The framers of the new income tax estimate that the superfluous personal incomes amount to over eight billion dollars annually, that is, the incomes which some 400,000 families possess beyond \$4,000

a year. This would allow four billion dollars a year for scientific research and the conservation of health and \$200 for each child beyond what is now spent on it. And why should not the money be so used? It would be the investment yielding the largest dividends. Those who spend \$4,000 a year already consume four times the average amount. Some may contribute more than four times the average amount to society, but they do so owing to the opportunity and advantage which society has given them. Thanks to the social order, those spending \$4,000 a year consume at least ten times as much as was possible for the average man a hundred years ago, and this possibility is due chiefly to the services of men now dead, most of all to those who advanced science and its useful applications. We can best reward them and honor their memory by using the wealth which they have created for further progress in the direction in which they led.

How long will it take to learn that the privileges of property are subordinate to the welfare of children? The average salary paid to teachers in the public schools of North Carolina is \$199, of Pennsylvania \$440, of California \$817. The state of Pennsylvania spends on its entire educational system less than one tenth of the value of the coal it mines. When a state consumes its natural resources it should reinvest their entire value in education, scientific research and the public welfare. In 1880 forty per cent. of the teachers in our public schools were men; now the percentage is under twenty; in New England and in New York it is under ten. In Germany four fifths of the teachers are men. Why should ignorant and characterless girls be permitted to practise education on our children because they are cheap? If the salaries of teachers were doubled, some competent men would adopt the profession

for a life work, and the best women could be selected, preferably those who had first cared for children of their own. The applications of science in the conservation of life and the production of wealth have entirely altered the position of women and of the family. In elementary schools the best teacher is the family—husband, wife and children together.

It is for the honor and ultimate welfare of Georgia that 25 per cent. of its population are children of school age, whereas only 17 per cent. of the population of New York and New England—probably less than 12 per cent. of their native population—are of this age. Since 1880 Georgia has increased its per-capita payment for public-school education sixfold; New York and New England have only doubled theirs. In the past twenty years New York and New England have not increased their expenditure enough to make up for the depreciation in the value of money. Georgia spends each year 6.3 mills on the assessed valuation of its real and personal property on public-school education, New York state 4.7 mills.² The south is bent under the inherited burden of slavery and civil war. But if it maintains its birth rate and cares properly for its children and its health, the center of wealth and civilization will return southward.

Over a billion dollars a year are spent in the United States on the drinking of alcohol and its consequences, a comparable amount on prostitution and its ensuing diseases. We devote twice as much money to each of these destructive agencies as to our entire educational work. Pleasure auto-

² Real estate is underassessed in Georgia. In New York personal property is scandalously understated, owing to the tax. Personal property in Massachusetts is valued at more than two thirds of the real estate, in New York at less than one twentieth.

mobiles or moving-picture shows cost each year more than the support of the teachers in all our schools. The national wealth is ample to double the salary of every teacher, from the negress in Georgia who receives \$100 a year to the professor at Harvard who receives \$5,000. The qualifications of the teacher should be as much above those of the lawyer and physician as they are now below them. The dentist who mends my children's teeth earns over \$20,000 a year; the professors and instructors who teach them at the university receive salaries averaging about \$2,000. Teaching can not be made the most honorable of professions by increasing salaries, but this is the easiest way to raise its standards. If we can bring into the work men of ability, they will promote the reforms that are needed. Teachers have inherited the status of domestic servants, and like domestic servants they should free themselves from personal subjugation. It may be that a hundred years hence the English suffragettes and the leaders of the I. W. W. will be counted among the world's reformers. But we can scarcely imagine that it will ever be looked back on as creditable that the salary and even the chair of a university professor should be dependent on the favor of a superior official, or that the educational authorities of our largest city should forbid the employment of married women as teachers; should permit a woman teacher to marry, but should discharge her if she bears a child.

Both the difficulties of state and endowed education and the possibilities of education in a democracy are exhibited by the performance of institutions such as the Scranton International School of Correspondence and Valparaiso University, which by the initiative of single individuals can compete successfully with all the resources of state support and private philanthropy. It is a triumph of democracy that such institu-

tions are possible; it is a scandal of democracy that they exist. The same observation may be made in regard to our private universities and the corporations for research established by Mr. Carnegie and Mr. Rockefeller. It is a fine thing that private means should be so used; it is humiliating that the taxation of steel and kerosene and the use of the proceeds should be left to individual caprice instead of being attended to by the state. Monopolies by which it is possible to charge more for a service than it costs must be controlled or conducted by the state. In like manner services rendered not to an individual but to society must be paid for by society. The most important of these services are creation in science and the bearing and rearing of children. Their performance is dependent on fundamental instincts implanted for their use to the race rather than to the individual and liable to atrophy or perversion under the artificial conditions of contemporary rationalism.

Under oligarchic institutions scientific research may be a by-product of the leisure classes and may be rewarded by patronage and honors; the bearing of children may be encouraged by non-rational patriotic and religious sanctions. In a democratic society research should be paid for by the state and the cost of bearing, rearing and educating children should be shared equally by all. Apart from the individual joy and profit in living—whatever that may be—each youth twenty years of age not below the average in endowment is economically worth to the state at least \$10,000 in that he will produce so much wealth in excess of what he will consume. The exceptional individual may be worth a hundred million dollars. It is the business of the state—its principal business—with one hand to provide for the advancement of the material sciences and the sciences concerned with human conduct, with the other hand to care

for the production of well-born children and their preparation for the work for which they are fit.

Existing conditions would be discouraging if they were a relapse from better things; but this is by no means the state of affairs. The defects of our system of education, our lack of distinction in science, art and letters, the shortcomings of our political and social institutions, are due in larger measure to the survival of standards and traditions from a pre-democratic world than to the difficulties inherent in a democracy. We may complain of our simplicity and crudeness, of our waste and incompetence, of our selfishness and corruption, but this only means that human nature and human conduct are what they are. Montesquieu was doubtless correct in saying that virtue is the principle of democracy, but of what social or political system is it not the basis? In what other nation would the people respond to the call of the primitive virtues with so much alacrity as here under the leadership of men such as Mr. Roosevelt, Mr. Wilson and Mr. Bryan? While virtue is essential to a nation, intelligence is desirable. The state should not neglect the advancement of science and be content to provide a hereditary system of education handed down from generation to generation. The Chinese have learned better.

The way to improve our educational work is to make the career of the teacher such that the wisest men and women of the country may be drawn to it, and then to give them opportunity and encouragement to develop a science of education and to apply it. In our universities, especially in our state universities, we have laid the foundations. The national government in its land grants to colleges of agriculture and the mechanic arts, in its bureau of education and in other directions, has ac-

complished something, but not enough. The secretary of a department of education and science should be the ablest man in the country, the president only excepted. The federal government can make the most noteworthy advance by the establishment of a national university at Washington to co-ordinate the work of its departments, to advance science and education, to set standards to the states. The ideals of a people must be symbolized in institutions. To substitute a constitution for a crown is futile. The ideals of a democracy can best be embodied in a great national university. We should then join with other nations in the establishment of an international university.

It is clearly impossible in a forty-minute address to discuss the contents and methods, the objects and results, of education, from the kindergarten to the university, from the crib to the death-bed. It is exactly those subjects on which we are most ignorant that can be talked about most endlessly. I have not hesitated to express opinions on various occasions³ and have indicated some of them in the course of these remarks. But my plea is that the time has now come when opinions, traditions and rule-of-thumb methods should yield to a science of education. Feeble infant as is this section of education of the American Association for the Advancement of Science, it has more promise of development than the best organized political party or the most richly endowed denominational church. It is the old story:—"The harvest truly is plenteous, but the laborers are few." If we could only realize what it would mean to have a science of education, a science of health, a science of conduct, surely all the resources of our civilization

³ For example, in three addresses published in *The Popular Science Monthly*, "Concerning the American University" (June, 1902), "The School and the Family" (January, 1909), and "The Case of Harvard College" (June, 1910).

would be turned in this direction. And they will be. The progress of the physical sciences in the nineteenth century will in the coming century be paralleled by advances in the psychological sciences. Science and education have given us democracy; it is the duty and the privilege of democracy to repay its debt by forwarding science and education to an extent not hitherto known in the world's history.

J. McKEEN CATTELL

THE PROFESSORSHIP OF PHILOSOPHY AND
PSYCHOLOGY AT LAFAYETTE
COLLEGE

At a largely attended joint meeting of the American Philosophical Association and the American Psychological Association, held at New Haven, December 31, 1913, the report of a committee appointed to inquire into the circumstances connected with the resignation of Dr. John M. Mecklin from the professorship of philosophy and psychology at Lafayette College was read and approved, *nemine contradicente*, and ordered printed. The committee was composed of Professors A. O. Lovejoy, of Johns Hopkins (*Chairman*), J. E. Creighton, of Cornell; E. Hocking, of Yale; E. B. McGilvary, of Wisconsin; W. T. Marvin, of Rutgers; G. H. Mead, of Chicago, and H. C. Warren, of Princeton. The report involves principles of general interest to American university teachers and administrators; and the more essential parts are, therefore, here reproduced at length.

The committee's understanding of the scope and purposes of its inquiry is set forth in its original letter to Dr. E. D. Warfield, president of the college:

The function of the committee is primarily to secure an authoritative statement of the facts in the case which can be laid before the members of the associations (of both of which Professor Mecklin is a member) at their approaching annual meetings, for their information. The concern of these bodies in the matter is twofold. They consist for the most part of members of the university teaching profession, and they are therefore anxious to ascertain the reason for any action which may have

the effect of injuring the professional standing and opportunities of any of their own members. It would seem, in the second place, desirable that the members of these associations should know somewhat definitely what doctrinal restrictions are imposed upon teachers and investigators in philosophy and psychology in the principal American institutions of learning. Such knowledge it is important to our members to have, both in order that their action in making recommendations for positions and the like may be guided thereby, and also that in their judgment of the department of philosophy and psychology in any institution, they may bear in mind the predetermined limits of liberty of opinion which affect the tenure of professorships in that institution. It has been publicly asserted that restrictions of this kind obtain at Lafayette College.

In its attempt to secure the desired information the committee, of course, turns first to yourself and to Professor Mecklin. We shall therefore be greatly obliged if you will let us know whether the statements already published in *SCIENCE* and the *Journal of Philosophy* regarding the circumstances of Professor Mecklin's resignation seem to you accurate, and what your understanding is as to the doctrinal requirements imposed upon professors of philosophy and psychology at Lafayette. The points about which we especially desire to be informed are indicated by the accompanying questions; we shall be obliged if, as an aid to giving definiteness to any statement which the committee may prepare on the subject, you will cover these questions in the reply which we hope you will be good enough to let us have.

The appended questions were as follows:

1. Was the resignation of Professor Mecklin called for by the administrative authorities of Lafayette (a) because of certain doctrines held or taught by him; or (b) because of certain doctrines contained in the text-books used by him?
2. In either case, what, specifically, were the opinions or teachings to which objection was made?
3. Are the statements made by Professor Mecklin in *The Journal of Philosophy* of September 25, 1913, regarded by the administrative authorities of Lafayette College as giving a substantially accurate and sufficient account of the facts in the case?
4. Is subscription to any specified creed a requisite to appointment to a professorship in Lafayette College?
5. Are the professors of philosophy and psychology required, so long as they hold their positions,

to conform their teachings to any specified creed or doctrine?

6. If so, what is this creed?

7. Are similar requirements imposed upon professors of other departments, such as biology and geology?

8. In case of alleged deviation by any professor from the doctrinal standards of the college, by whose interpretation of these standards is such deviation determined?

To these inquiries the committee reports that it has been unable to secure any definite answers from the president of Lafayette. After a month's delay, a reply to the above letter signed by President Warfield, the president of the board of trustees and the chairman of the curriculum committee, was received; but it "could be construed by the committee only as a courteous declination to furnish the definite information desired." A subsequent letter from President Warfield "accentuated this declination." The first of these communications does, however, contain at least one statement which a member of the board of trustees formally declares to the committee to be "not in accordance with the facts." In spite of this refusal of information by the college administration, the committee secured a large mass of evidence from other sources—trustees, members of the faculty, and former students under Professor Mecklin—and arrived at certain conclusions bearing upon three general questions. The committee's findings upon each of these are in part as follows:

I. *What, before the present case arose, has been the accepted understanding as to the limits of freedom in philosophical and psychological teaching at Lafayette College?*

American colleges and universities fall into two classes: Those in which freedom of inquiry, of belief and of teaching is, if not absolutely unrestricted, at least subject to limitations so few and so remote as to give practically no occasion for differences of opinion; and those which are frankly instruments of denominational or political propaganda. The committee does not consider itself authorized to discuss the question whether the existence of both sorts of institution is desirable. If, therefore, the present case were one in which a teacher in a professedly denominational college had in his teaching expressly repudiated some

clearly defined and generally accepted doctrine of that denomination, the committee would not feel justified in proceeding further with the matter. These associations should, in the committee's opinion, intervene in questions of this sort only for three ends: (1) To ascertain which institutions do, and which do not, officially profess the principle of freedom of teaching; (2) to ascertain, with a fair degree of definiteness, in the case of those institutions which do not, what the doctrinal limitations imposed upon their teachers of philosophy and psychology are; and (3) to call attention publicly to all instances in which, in institutions of the former sort, freedom of teaching appears to have been interfered with, or in which, in institutions of the latter sort, restrictions other than those antecedently laid down appear to have been imposed.

Upon the question whether Lafayette is to be classed with institutions of the first or second type, the committee finds a surprising measure of disagreement among officers, teachers and graduates of the college. Article VIII. of the college charter provides:

"That persons of every religious denomination shall be capable of being elected trustees, nor shall any person, either as principal, professor, tutor or pupil, be refused admittance into said college, or denied any of the privileges, immunities or advantages thereof for or on account of his sentiments in matters of religion."

In accordance with this clause of the charter, a trustee writes the committee as follows:

"I need not remind you that Lafayette College is not a theological institution, nor does it profess to teach or impose upon its teachers or students, any creed or doctrinal religious standards. . . . Whatever may be Dr. Mecklin's impression of the attitude of the president, so far as the trustees and faculty of the institution are concerned, I know of no policy or shaping thereof that in any way involves the recognition or inculcation of any sectarian creed, Presbyterian or otherwise, much less any particular type of Presbyterianism." This interpretation of the charter—which is obviously in harmony with its text—is evidently shared by other members of the board of trustees.

On the other hand, the testimony of some members of the faculty, and that of President Warfield and two trustees, is that there is a general assumption that the teaching of professors must be in harmony with the doctrinal standards of the Presbyterian Church. The General Catalogue

(1912-13) contains the following statement (p. 146):

"The aim of Lafayette College is distinctly religious. Under the general direction of the Synod of Pennsylvania of the Presbyterian Church, its instruction is in full sympathy with the doctrines of that body. At the same time religious instruction is carried on with a view to a broad and general development of Christian character, within the lines of general acceptance among Evangelical Christians, the points of agreement, rather than those of disagreement, being dwelt upon."

The last sentence would appear to indicate the understanding upon which Professor Mecklin accepted the call to the professorship of philosophy and psychology in 1904; he writes that he then and at all times recognized that his teaching, "as well as that of every other professor," was to be "in accord with Christianity in the broad Evangelical interpretation of that term."

Here, then, would appear to be three distinct views of the position and policy of the college: It is committed to no specific creed; it is committed only to the principles of "Evangelical Christianity"; and it is committed to the principles of the Presbyterian Church. The committee, for the rest of this report, assumes that substantially the last-mentioned view is to be taken as the answer to the first question,—that, in the words of a trustee, it has been "commonly understood that the teachings in such departments [*i. e.*, those of philosophy and psychology] are in general to be in harmony with the doctrines of philosophy usually taught and held in the Presbyterian Church." But the committee can not but think it highly undesirable that in any college a question of such importance should be left open to such divergent official answers; and it appears of doubtful legality that the prevailing practise in the matter should be in express contradiction with an unreppealed clause in the college charter.

II. The second question which the committee has endeavored to answer is: *What were the actual grounds upon which Professor Mecklin's resignation was asked for, and what do these indicate as to the doctrinal limitation imposed upon professors in philosophy and psychology under the present administration of the college?* Upon this the committee's findings are as follows:

1. No connected and altogether definite statement seems ever to have been formulated of the specific points in Professor Mecklin's teaching to which objection was made, or of the manner in

which these were held to conflict with Presbyterian principles. A member of the board of trustees of the college, who was present at the meeting of the curriculum committee at which the matter was first brought forward, states that he was unable from the discussion at that meeting, or in any other way, to ascertain precisely on account of what charges as to doctrines held or taught by him Professor Mecklin was dismissed. This trustee writes that the accusations of erroneous doctrines or opinions made against Professor Mecklin at this meeting "were indefinite and as far as I am concerned remain so to this present time." Another correspondent conversant with the facts writes the committee that the president of the college simply asserted that "the doctrines set forth in certain text-books adopted by Professor Mecklin, viz., Angell on Psychology, Dewey and Tufts on Ethics, McDougall on Social Psychology, and Ames on the Psychology of Religious Experience, were a departure from the doctrines that had been taught in the college in previous years. No definite statement was ever made by the president to the board of trustees, so far as I recollect, of the exact teachings to which he made objections, other than the general objections to the text-books above mentioned, and a general and indefinite statement that the teachings of Professor Mecklin were not in harmony with the traditional teachings of the college in the department of philosophy. Previously to Professor Mecklin's occupying the chair of philosophy, the teaching in that department had for some years been by Presbyterian clergymen who devoted a portion of their time thereto, but did not undertake to present to the student any clearly defined system of philosophical instruction. Professor Mecklin undertook to introduce such a system of instruction, in line with other first-class educational institutions, some of which were well-known Presbyterian colleges, and used in connection therewith, among others, the text-books above mentioned. Some of his teachings as inferred from the said text-books were objected to by the president as contrary to the traditional teaching of the college on these subjects. The board of trustees did not pass upon the questions raised, although they discussed them, and there was a difference of opinion among them on the subject. Some of the trustees, feeling it desirable that a controversy of a religious or denominational aspect should be avoided, thought it wisest, in view of all the circumstances, to advise Professor Mecklin to resign rather than have the

discussion proceed to a vote, which might or might not have been in his favor." There seems, in short to be no general and clear understanding among the members of the board of trustees and the faculty of the college as to the precise doctrinal grounds upon which the president's insistence on Professor Mecklin's dismissal was based. It is the opinion of the committee that in no institutions, of whatever type, should a professor be compelled to relinquish his position for doctrinal reasons, except upon definite charges, communicated to him in writing and laid, with the supporting evidence, before the entire board of trustees and the faculty; and that it is unfortunate in any case of this kind that, even by agreement between the persons concerned, the matter should fail to be brought to an explicit issue before the responsible governing body of the institution.

The committee, however, reports that, so far as can be determined in the absence of definite charges, the president's original and decisive objection to Professor Mecklin's teaching was, in the words of another professor at Lafayette, "based upon Dr. Mecklin's use of the doctrine or theory of evolution in his discussion of the growth of religion."

The committee observes that "as a body it has no competency to discuss whether or not the doctrines and text-books in question are or are not in harmony with Presbyterian standards." With regard, however, to the restrictions now imposed at Lafayette the committee reports as follows:

The committee is forced to conclude that at Lafayette College at the present time tenure of the professorship of philosophy and psychology is, in practise, subject not only to the requirement that the teachings of the incumbent shall be in substantial harmony with the commonly accepted doctrines of the Presbyterian Church, but also to the requirement that his teachings shall be in substantial harmony with the theological opinions of the administrative authorities of the college, and with their interpretation of the philosophical implications of those opinions. The committee also concludes that the statement of the Lafayette College Catalogue, that the religious instruction there "is carried on within the lines of general acceptance among evangelical Christians, the points of agreement, rather than those of disagreement, being emphasized," is not accurately descriptive of the present policy and practise of the college. The

committee further gathers from various evidence brought to its knowledge that the administration of the college disapproves of the mere presentation to the students, through text-books or collateral reading, of any philosophical views which it regards as seriously erroneous, and discourages instruction which has the effect, as Professor Mecklin's evidently had, of provoking thought and stimulating discussion and debate among the students upon philosophical and religious issues.

III. The third general question taken up by the committee concerns the attitude of the administrative authorities of Lafayette College towards the committee's inquiry. This attitude, as indicated above, was one of unwillingness to give the information asked for. Upon this the report makes the following comments:

It is true that President Warfield [in his last letter to the committee] gives as a reason for his refusal to make "a statement with regard to these matters" a formal request by "those who were recognized as speaking for Professor Mecklin" that "no information should be given out with regard to what took place before the board of trustees except that after the consideration of a report from the curriculum committee Dr. Mecklin offered his resignation which was accepted and that he was granted a year's salary." President Warfield thus represents his reticence as actuated, at least in part, by a deference to Professor Mecklin's wishes. Upon this matter Professor Mecklin makes the following statement to the committee: that no such request was made to the trustees by his authority, that, on the contrary, he regarded such a policy of secrecy about the causes and circumstances of his resignation as unfair to him and likely to be detrimental to his professional reputation; that he expressly informed a committee of the trustees which conferred with him that he desired no concealment of the grounds for the action taken; that he has publicly given evidence that such was his desire, by his letter on the case, published in *The Journal of Philosophy*; and that his wish that the facts should be fully made known has come within the knowledge of President Warfield. Your committee notes, also, that there was published in the Philadelphia *Public Ledger* of June 20, 1913, a long and circumstantial (though incomplete) statement (already referred to) by Dr. Warfield respecting Dr. Mecklin's resignation; it can not, therefore, be said that hitherto "no information" has been "given to the public with regard to what took place be-

fore the board of trustees," beyond that contained in the letter above cited. In view of these circumstances the committee finds itself unable to suppose that the decisive reason for President Warfield's reluctance to answer its inquiries is his consideration for the interests and wishes of Professor Mecklin. The committee notes, moreover, that two out of the three questions last laid before President Warfield asked for information, not about the resignation of Professor Mecklin, but about the general policy of the college and the specific credal requirements attaching to the professorship of philosophy and psychology. These inquiries, also, President Warfield has declined to answer. He intimates, indeed, that he regards it as improper for persons not connected with the college to ask, or for him to answer, "questions concerning the college or its members."

The attitude thus assumed does not seem to this committee one which can with propriety be maintained by the officers of any college or university towards the inquiries of a representative national organization of college and university teachers and other scholars. We believe it to be the right of the general body of professors of philosophy and psychology to know definitely the conditions of the tenure of any professorship in their subject; and also their right, and that of the public to which colleges look for support, to understand unequivocally what measure of freedom of teaching is granted in any college, and to be informed as to the essential details of any case in which credal restrictions, other than those to which the college officially stands committed, are publicly declared by responsible persons to have been imposed. No college does well to live unto itself to such a degree that it fails to recognize that in all such issues the university teaching profession at large has a legitimate concern. And any college hazards its claim upon the confidence of the public and the friendly regard of the teaching profession by an appearance of unwillingness to make a full and frank statement of the facts in all matters of this sort.

The report is published in full in the *Journal of Philosophy, Psychology and Scientific Methods* for January 29, 1914.

SCIENTIFIC NOTES AND NEWS

DR. CALVIN MILTON WOODWARD, emeritus professor of mathematics and applied mechanics and dean of the school of engineering and architecture of Washington University, past

president of the American Association for the Advancement of Science, of the board of regents of the University of Missouri and of the St. Louis Board of Education, died from apoplexy on January 12, aged seventy-seven years.

SIR DAVID GILL, the distinguished British astronomer, for many years astronomer at the Cape of Good Hope, died on January 24, at the age of seventy years.

COLONEL WILLIAM C. GORGAS has been nominated to be surgeon-general of the army of the United States, with the rank of brigadier-general.

DR. S. S. GOLDWATER has been appointed commissioner of health for New York City to succeed Dr. Ernst J. Lederle.

CHARLES W. ELIOT, president emeritus of Harvard university, had been elected a trustee of the Rockefeller Foundation for the term of three years.

DR. J. S. HALDANE, reader in physiology at Oxford, has been chosen as Silliman lecturer at Yale University for next year.

THE organizing committee, selected by the American members of the international committee of the Second International Eugenics Congress, has met in New York City and unanimously elected Dr. Henry Fairfield Osborn as president of the congress. Dr. Alexander Graham Bell was elected honorary president. The congress will be held in New York City near the end of September, 1915.

PROFESSOR ANDREW C. McLAUGHLIN, head of the department of history in the University of Chicago, was elected president of the American Historical Association at its recent meeting in Charleston, South Carolina.

At the recent annual meeting of the American Anthropological Association held in New York City, Professor Roland B. Dixon, of Harvard University, was reelected president; and Professors Franz Boas, of Columbia University, and George Grant MacCurdy, of Yale University, were designated to represent the association at the International Congress of Americanists, to be held in Washington, D. C., October 5 to 10, 1914.

WE learn from *Nature* that an institution of petroleum technologists has been formed in London with Sir Boverton Redwood, Bart., as president. Dr. D. T. Day, of the U. S. Geological Survey, and Professor C. Engler have been elected honorary members.

THE Geological Society of London will award its medals and funds as follows: Wollaston medal, Dr. J. E. Marr, F.R.S.; Murchison medal, W. A. E. Ussher; Lyell medal, C. S. Middlemiss; Wollaston fund, R. B. Newton; Murchison fund, F. N. Haward; Lyell fund, Rev. W. Howchin and J. Postlethwaite.

THE prizes in astronomy of the Paris Academy of Sciences have been awarded as follows: the Lalande prize to J. Bosler, for his researches on the sudden variations of terrestrial magnetism and their connection with disturbances in the sun; the Valz prize to Professor Fowler, for his researches in spectroscopy; the G. de Pontecoulant prize to M. Sundmann, for his researches on the problem of three bodies.

DR. ALŠĚ HRDLÍČKA, of the U. S. National Museum, has been named a titular member of the Société Impériale Des Amis D'Histoire Naturelle, D'Anthropologie et D'Ethnographie, Moscow, Russia.

PROFESSOR W. C. FISCHER, recently compelled to relinquish his chair at Wesleyan University, was a candidate for mayor of Middletown at a recent election, but was defeated by a vote of 699 to 689.

DR. CARL SKOTTSBERG, lecturer on botany and keeper of the herbarium at the University of Upsala and Dr. C. H. Ostenfeld, of the Botanical Museum at Copenhagen, have been visiting American botanical institutions.

As the first half of the Washington-Paris longitude campaign has been completed, the last few weeks have been devoted for the most part to exchange of observers. Mr. G. A. Hill and his party have returned to Washington, and the party headed by Professor F. B. Littell, U. S. N., has departed for Paris. The new French representatives are Professor E. Vignet, of the Paris Observatory, and Ensign P. Auverny, of the French navy.

NEWS has been received from Dr. William E. Farabee, who is now in Brazil directing the University of Pennsylvania Expedition in the Amazon regions. The expedition had passed through the territory inhabited by the Macusi Indians, and was starting, with forty porters, through the Wai Wai country into unexplored parts of French and Dutch Guiana.

DR. W. T. HORNBADAY, director of the New York Zoological Park, will give a course of lectures as a part of the regular work at the Yale Forest School on wild animal life and its conservation. The titles of the five lectures in the course are as follows: "The Extinction of Valuable Wild Life," "The Feathered Allies of the Farmer and Forester," "The Legitimate Utilization of Wild Birds and Mammals," "Wild-animal Pests and their Rational Treatment," "The Duty and Power of the Citizen in Wild Life Conservation."

A COURSE in industrial organization and scientific management will be given at Brown University during the second semester of the present year. A feature of the course will be three or four lectures monthly by business men and efficiency experts. The first of these lectures, which will be open to the public, will be given on February 19 by Professor H. S. Person, director of the Tuck School of Administration and Finance, Dartmouth College, on "Different Types of Management."

ON January 8 Professor Theobald Smith delivered a lecture on "Prophylactic and Therapeutic Vaccines" before the New York State Veterinary College at Cornell University.

DR. ARTHUR L. DAY, director of the Geophysical Laboratory of the Carnegie Institution of Washington, lectured before the Geographical Society of Chicago on January 23 on "Some Observations on the Volcano Kilauea in Action."

MR. FRANCIS S. PEABODY, president of the Peabody Coal Company of Chicago, Illinois, recently gave a lecture before the college of engineering of the University of Illinois on "The Mining and Utilization of Illinois Coal." The lecture was illustrated with excel-

lent motion pictures taken underground in actual coal mines. They are the first successful motion pictures taken underground, and they give a vivid idea of the actual conditions met in coal mining.

ON January 20, Professor W. Bateson began a course of six lectures at the Royal Institution on animals and plants under domestication. Beginning on January 22, Mr. W. McDougall gave a course of two lectures on the mind of savage men. The Friday evening discourse on January 23 was delivered by Sir James Dewar on "The Coming-of-age of the Vacuum Flask."

A MEMORIAL to Captain Scott will be unveiled on February 5 on the Col de Lautaret in the French Alps, whither the British explorer went in March, 1908, to make a trial of his motor sleighs.

JOHN JAMES RIVERS, born in England on January 6, 1824, known for many years as a naturalist on the Pacific coast, died at his home in Santa Monica, California, on December 16, 1913.

THE death has occurred, in his eighty-fourth year, of Mr. John Phin, the author of popular scientific books, and formerly editor of several New York technical papers.

THE death is announced of Dr. A. F. Le Double, professor of anatomy at the School Médecine in Tours, France. Professor Le Double was an indefatigable worker and published a number of works of special value to anatomy and anthropology on the variations of the muscular system, of the bones of the skull, those of the face and those of the spine. Death overtook him in the sixty-sixth year of age and in the midst of preparation of further work on the variations of the human system.

THE U. S. Civil Service Commission announces an examination for assistant in road economics, to fill a vacancy in this position in the office of public roads, Department of Agriculture, Washington, D. C., at a salary of \$1,500 a year.

THE council of the Royal Geographical Society has made a grant of £1,000 towards the

expenses of Sir Ernest Shackleton's trans-antarctic expedition.

WORK has begun on the Magee Hospital for maternity cases at Pittsburgh to be erected at a cost of \$800,000 provided by the late Christopher L. Magee as a memorial to his mother. The hospital is affiliated with the school of medicine of the University of Pittsburgh.

MESSRS. SAMUEL and HARRY SACHS, to perpetuate the memory of their parents, the late Joseph and Sophie Sachs, have given to Mount Sinai Hospital, New York, the sum of \$125,000 to endow two neurological wards. The hospital will receive the sum of \$100,000 under the will of Benjamin Altman and has received a \$100,000 legacy from Mrs. Louis W. Neustader.

THE Russian ministry of the interior has given consent to the free admission of Jewish members of the twelfth International Ophthalmological Congress, to be held at St. Petersburg from July 28 to August 2, but it limits the time they can stay in the country to September 15. In view of this restriction, Professor Julius Hirschberg, president of the Berlin Ophthalmological Society, has proposed that ophthalmologists should refrain from attending the congress.

MARCHESE RAFFAELE CAPELLI, president of the tenth International Congress of Geography, has communicated to the U. S. Geological Survey, the following resolution adopted by the recent congress, on motion of M. Le General Schokalsky:

The Tenth International Congress of Geography approves the impulse given to the project of an atlas of forms of terrestrial relief and the commencement of the execution of the work. It strongly recommends to all geographers and to the scientific institutions to aid this enterprise in every manner.

He requests that wide circulation be given to this resolution of the congress, in order to obtain cooperation on the part of the geographers of different countries.

IN accordance with plans recently formulated by a special committee appointed by the secretary of agriculture whose recommenda-

tions have been approved by him, announcement is made of a general change to begin January, 1914, in the character of the *Monthly Weather Review* and the *Bulletin of the Mount Weather Observatory*. These two periodicals which have hitherto appeared separately (i. e., the *Monthly Weather Review*, largely devoted to statistical data and notes on current weather conditions, and the *Bulletin of the Mount Weather Observatory*, embodying a portion of the research work done by the bureau) will be merged into a single publication. The new series will retain the former well-known title, *Monthly Weather Review*. It will contain contributions from the officials of the Weather Bureau engaged in research work of any kind bearing on the atmosphere, and its pages will be open also to others working along similar lines. It will not contain the detailed tables for the twelve large climatological districts that have appeared in the *Review* since July, 1909, but tables giving a general summary of the data from the "full reporting stations" of the Bureau, about 200 in number, will still appear as in the past. Beginning with January, 1914, the statistics now assembled to form these detailed tables for the twelve large climatological districts, defined by great watersheds, will continue to be assembled in tables similar to these, but will be arranged by states instead of districts. The tables for each state will form one report prepared at the section center of that state, except in the case of the New England States, which will appear as a single section; and Maryland, Delaware, and the District of Columbia will also be grouped into a single section. The total number of these sections will be 42. These detailed summaries by states will each contain from 8 to 12 pages of data and charts and will be issued from ten to twenty days after the close of each month; they will thus meet the need for prompt dissemination in each state of the information they contain better than is possible under the present policy of collecting them at the Central Office into a single monthly.

THE Russian empire, covering one seventh of the land area of the globe and only sparsely

settled in spite of its nearly 170,000,000 inhabitants, offers an interesting subject for study for both business men and economists. This country to-day presents a picture of economic development comparable with that of the United States of three or four generations ago, in that Russia is now chiefly a producer of the raw materials derived from nature, such as grain, timber, hides and minerals, and is just beginning to develop manufacturing industries of importance. Its exports are almost entirely foodstuffs and raw and semi-manufactured products, while it imports nearly all of the higher grades of manufactures which its people require. The total value of the foreign trade of European Russia, in 1912, according to official figures, was more than \$1,200,000,000, in which the United States participated to the extent of only \$53,000,000. However, the indirect trade between the two countries passing through foreign middlemen brings the value of the sales of American products to Russia to \$80,000,000, and the exports from Russia to the United States to \$30,000,000. Largely owing to the lack of knowledge among American business men of the possibilities of the Russian market, the trade between the two countries is on the threshold only of its possible development. The monograph on Russia just published by the Bureau of Foreign and Domestic Commerce, of the Department of Commerce, entitled "Handbook on Russia," should therefore be of special interest. This book contains nearly 260 pages, with two maps, and includes a comparative description of the economic situation in European Russia, by Consul General John H. Snodgrass, stationed at Moscow; reviews of the commerce of various districts in 1912, by the American consuls stationed in Russia, and a very timely description of commercial and industrial conditions in Siberia, by Consul John Jewell, stationed at Vladivostok. To those who still regard that country as a frozen waste, the picture presented by Mr. Jewell will be a revelation. He compares Siberia to-day with Canada of a generation ago, and points out the possibili-

ties of great trade development that lie in the great natural resources of the country.

The committee appointed by the Paris Academy of Sciences to allocate the grants from the Bonaparte Fund for the year 1913 have, as we learn from *Nature*, made the following proposals: Out of sixty-three applications the committee recommends twenty-one grants.

3,000 francs to H. Caillol, for the publication of his catalogue of the Coleoptera of Provence.

2,000 francs to A. Colson, for apparatus required for his work in physical chemistry.

2,000 francs to E. Coquidé, to assist him in his study of the means of utilizing peaty soil.

2,000 francs to C. Schlegel, for the continuation of his researches in the laboratory of M. Delage.

6,000 francs, in equal parts, between MM. Pitard and Pallary, for assistance in the continuation of their scientific work in Morocco.

2,000 francs to Jules Welsch, for his geological work on the coasts of western France and Great Britain.

2,000 francs to Louis Roule, for continuing and extending his researches on the morphology and biology of the salmon in France.

2,000 francs to Jean Pougnet, for the continuation of his researches on the chemical and biological action of ultra-violet light.

2,000 francs to C. Dauzère for his work on cellular vortices.

2,000 francs to Méd. Gard, for the publication of a work and atlas on material left by the late M. Bornet.

4,000 francs to Aug. Chevalier, to meet the expense necessitated by the classification of the botanical material arising from his expeditions in Africa.

2,000 francs to Paul Becquerel, for the continuation of his physiological researches relating to the influence of radio-active substances upon the nutrition, reproduction and variation of some species of plants.

4,000 francs to Le Morvan, for assistance in publishing the photographic atlas of the moon.

2,000 francs to Jacques Pellegrin, to assist

him to pursue his researches and publish works on African fishes.

3,000 francs to E. Rengade, for a systematic research on the presence and distribution of the rare alkali metals in mineral waters.

3,000 francs to Charles Alluaud, for the publication of work on the Alpine fauna and flora of the high mountainous regions of eastern Africa.

2,000 francs to Charles Lormand, for the purchase of a sufficient quantity of radium bromide to carry out methodical researches on the action of radio-activity on the development of plants.

2,000 francs to Alphonse Labbé, for researches on the modifications undergone by animals on changing from salt to fresh water or the reverse.

3,000 francs to G. de Gironcourt, for the publication of the scientific results of his expeditions in Morocco and western Africa.

3,000 francs to A. F. Legendre, for the publication of maps and documents of his expeditions in China.

2,000 francs to H. Abraham, for the determination of the velocity of propagation of Hertzian waves between Paris and Toulon.

UNIVERSITY AND EDUCATIONAL NEWS

THE General Education Board has given \$750,000 toward an endowment of \$1,500,000 for the medical department of Washington University, St. Louis, to create full time teaching and research departments in medicine, surgery, and pediatrics. The conditions of the gift provide that all teachers in these departments, while free to render any medical or surgical service, must not derive therefrom any personal gain. Their entire time must be devoted to hospital work, to teaching and research in their several specialties, as it is believed that medical education in the past has suffered from the fact that the teachers have had to rely on private work for the major portion of their income. The General Education Board has also made conditional grants of \$100,000 each to Knox College, Galesburg, Ill., and to Washburn College, Topeka, Kan.

ANNOUNCEMENT was made at a meeting of the Yale Corporation on January 19 that gifts and pledges of \$350,000 had been obtained for the development of the Yale Divinity School into a university school of religion. These gifts will increase the endowment of the school to over \$1,200,000. Among the gifts were \$100,000 from Mrs. D. Willis James and Arthur Curtiss James, of New Haven; \$80,000 from Mrs. Stephen Merrell Clement, of Buffalo, N. Y., and an anonymous gift of \$100,000, the latter to found a chair of social service.

THE trustees of Vassar College have announced that as President Taylor's resignation, which he presented a year ago, is to take effect February 1, in accordance with his wishes, and as no new president has been appointed, the administration of the college will be carried on by committees of trustees and faculty. Professor Herbert E. Mills, head of the department of economics, will act as chairman of the faculty.

ON January 9 and 10 occurred the first annual convention of the Stevens Institute of Technology. The convention opened with a symposium on "An Engineer's Part in the Regulation of Public Utilities." President Humphreys acted as chairman of the meeting, and papers were read by him and by several other Stevens alumni. Other features of the convention were the midwinter alumni meeting, a conference of Stevens Clubs, a trip to the Brooklyn Navy Yard and the alumni dinner at the Hotel Astor.

DR. E. A. FATH, director of Beloit College Observatory, has resigned his position to accept the presidency of Redfield College of Redfield, S. D. He will take up his new work about March 1.

DR. HENRY WINSTON HARPER, professor of chemistry in the University of Texas, Austin, has been made dean of the graduate department.

DR. CREIGHTON WELLMAN, dean of the school of hygiene and tropical medicine of the Tulane University of Louisiana, has resigned this position.

PROFESSOR F. L. STEVENS has resigned the position of dean of the College of Agriculture, Mayaguez, Porto Rico, to become professor of plant pathology in the University of Illinois.

DR. WILLIAM DUANE has been appointed assistant professor of physics in Harvard University. He has spent six years in the Curie Radium Laboratory at Paris, and last fall returned to this country as research fellow of the cancer commission of Harvard University. Professor Duane will devote the greater part of his time to the physiological action of radioactive substances and to the problems in physics directly connected with this subject at the Harvard Medical School and at the Huntington Cancer Hospital, but he will also undertake the direction of advanced students in problems on the purely physical side of radioactivity in the Jefferson Physical Laboratory.

DR. H. F. BAKER, F.R.S., fellow and lecturer of St. John's College, and Cayley university lecturer in mathematics, has been elected Lowndean professor of astronomy and geometry at the University of Cambridge in succession to the late Sir Robert Ball.

DISCUSSION AND CORRESPONDENCE

TUBERCULOSIS FOLLOWING TYPHOID FEVER

IN SCIENCE for 1908, Professor W. T. Sedgwick, of the Massachusetts Institute of Technology, called attention to the remarkable discovery by Reincke, of Hamburg, and Mills, of the United States, that when an infected water supply of a community was improved by filtration or otherwise, not only did typhoid fever diminish, but other diseases also, such as tuberculosis. Hazen calculated that for every typhoid death prevented, two or three were saved from death by other diseases. Sedgwick and MacNutt subsequently published their full paper in the *Journal of Infectious Diseases*, and the former in still another paper in a symposium on "Tuberculosis in Massachusetts," 1908, stated that as a rule infected waters increased the death rate from tuberculosis and purification of water decreased the rate.

For some time I have been collecting data which enable us to extend these generalizations still further. It has been found that tuberculosis follows typhoid fever far more frequently than physicians have suspected, and moreover the tuberculosis mortality curve of a nation is almost always parallel to that of typhoid fever. Cities do not show such a close agreement as the country as a whole, because consumptives quite commonly leave the city to die elsewhere. As far as the very defective statistics permit a conclusion, it is to the effect that consumptives have had much more typhoid fever than the rest of the population. We have long known of the serious after effects of typhoid fever, but only recently have a few physicians been calling attention to the far-reaching nature of these sequelæ. Tuberculosis is only one of these results. That is, by reducing typhoid fever in any way whatever we save far more from death by numerous other conditions due to the lessened resistance caused by the typhoid infection. The purification of a water supply is then only one of the numerous ways of reducing tuberculosis.

The explanation of the phenomenon is evident. By personal inquiries of physicians in the United States, Germany, Switzerland, France and Great Britain, I find that the following facts seem proved to the minds of those who by special study are competent to form an opinion. Babies are born free of tuberculosis, but begin to acquire it as soon as they can crawl around, pick up the bacilli with dust and dirt, and immediately convey them to the mouth after the manner of all babies. These germs are weakened or attenuated by sunlight, drying, etc., and are not able to spread actively, though they establish themselves. Those which are taken in by the phagocytes have the same effect as vaccination and cause the production of antibodies which make us all more or less immune to infection by virulent bacilli. If a baby is infected by fresh virulent bacilli from a nurse, before its immunity is produced, it dies of rapid disseminated tuberculosis, but an adult is not harmed by the virulent bacilli he takes in.

Indeed, there is no incontrovertible evidence that any adult ever acquires tuberculosis. If one develops active tuberculosis, it is not a new infection, but an activation of latent lesions he has been carrying since childhood. Something has happened to him which has caused a temporary lessening of his antibodies and allowed the latent tuberculosis to spread—and nothing is more potent in doing this than the infections like measles, whooping cough and typhoid fever. Without these activating causes a man may lose immunity very slowly by improper food, mental and physical exhaustion, living in badly ventilated rooms, lack of outdoor exercise and a thousand other ways of lowering general health, but if one in such a condition does acquire another infection like pneumonia, typhoid fever or influenza, his chances of becoming actively tubercular later are very large. Post-mortems of children almost always reveal tubercle, no matter what the disease was which caused death. Post-mortems of adults always show healed lesions, proving that at some time in our lives each of us lost resistance sufficiently to allow the lesions to become active, though we were later cured by a reestablishment of the immunity. One eighth or one tenth of us are unable to reestablish it and perish from tuberculosis. The facts are bound to modify the anti-tuberculosis crusade most profoundly.

Savages, living an outdoor isolated life, have no chance to encounter tubercle bacilli and consequently do not become immune. When they do come in contact with a case they run a rapidly fatal course—generally if not always disseminated or miliary. That is, tuberculosis did not become a human affliction until long after we began to cluster together in confined shelters—possibly not until after we began to construct huts, “dugouts” and houses.

The detailed data which prove the relationship of tuberculosis and typhoid fever will appear in *American Medicine* in January, but this preliminary note is published as an answer to the questions of Hazen and Sedgwick as to how we could explain the phenomenon of a decrease of tuberculosis by the

simple expedient of purifying the water supply.

CHARLES E. WOODRUFF

SCIENTIFIC BOOKS

Lectures on the Differential Geometry of Curves and Surfaces. By A. R. FORSYTH. University Press, Cambridge, 1912. Large octavo. Pp. xxiii + 585. Price, \$8.

Professor Forsyth's skill and versatility in the writing of mathematical treatises, already proved by his well-known works on differential equations and the theory of functions, is again illustrated by this new volume, his first in the field of geometry. The lectures were delivered, in substantially their present form, during the author's tenure of the Sadlerian professorship at Cambridge. They make very interesting reading. The style is graceful, and the technical discussions are illuminated by many passages on the history and development of the special topics considered.

Naturally no attempt is made to cover the whole field of differential geometry. Not even the classic four-volume treatise of Darboux pretends to include all the applications of the methods of the infinitesimal calculus to the domain of geometry. In particular, the author omits all extensions to hyperspace and non-Euclidean geometries. His main aim is to "expound those elements with which eager and enterprising students should become acquainted," and to provide such students, who, later, may devote themselves to original work "with some of the instruments of research."

The author restricts himself to curves and surfaces in ordinary Euclidean space and uses the direct methods introduced by Gauss. "I have made no attempt to give what could only have been a rather faint reproduction of Darboux's treatment, which centers round the tri-rectangular trihedron at any point of a curve or surface or system. My hope is that students may experience an added stimulus when they find that different methods combine in the development of growing knowledge." It must be admitted that, by showing the power of the more natural methods (combined, of course, with typical Cambridge skill in

analytical manipulation) in the solution of extremely difficult problems, the author's procedure is amply justified.

As regards logical rigor the work is about on a level with the texts of Bianchi, Scheffers, and Eisenhart. No attempt is made to lay precise function-theoretic foundations for the geometric structure which is erected. In particular the concepts of analytic curve and surface, employed throughout the work, are never formulated precisely. Professor Study's vigorous criticism of the new edition of Bianchi in this aspect applies in fact to all standard treatises on differential geometry. It must be confessed that the claims of rigor are not emphasized in geometry to nearly the same extent as in analysis. In this respect geometry in fact occupies a position between analysis and physics, and to that extent belongs to applied rather than to pure mathematics. Study has himself outlined a proper basis for the treatment of analytic curves,¹ but this has not yet been digested into a form suitable for an introductory text, and the corresponding discussion of surfaces is still to be undertaken. No doubt, in the future—how near one can not say—Study's high and beautiful ideal will become realized. Meanwhile, most geometers, at least when they write on differential geometry, follow the older and what they considered the most expedient approach. Perhaps a distinction should be made, even in the domain of graduate mathematics, between *pedagogic* books and *logical* books. The evolution toward a rigorous treatment (never perfect, but at least up to the highest standard of a given period of mathematics) is obviously inevitable.

As regards the introduction of *imaginary* configurations in geometry the author follows the traditional half-hearted policy of considering them only when it is convenient, or at least traditional, to do so. Thus, in connection with a real surface, it is analytically expedient to introduce certain curves, of course imaginary, whose length (between any two points) is zero. [These the author design-

¹ In two memoirs published in the *Trans. Amer. Math. Soc.*, 1909, 1910.

nates as *nul* lines, a very good name in itself, but already in use in an entirely different sense in connection with the so-called nul-system of statics and line geometry, and furthermore unnecessary since the term *minimal* lines is quite standardized in the literature.] Again in connection with the problem of geodesic representation, the usual discussion of the real solutions of Beltrami and Dini is followed by the imaginary solutions discovered by Sophus Lie. If then imaginary figures are allowed even when, as in this last instance, they are, however interesting, really inconvenient, why not, as Study advocates, introduce them deliberately and systematically?

The student usually gets the impression that whatever is true in the real domain, will, by some very nebulous principle of continuity, also be true in the larger complex (real and imaginary) domain. This is actually the case in a remarkably large number of questions, but certainly not in all. The exceptional character of minimal curves has long been recognized, but only recently the peculiar curves lying in a minimal plane have been investigated by Study and his students.

Even in the domain of curves lying in an ordinary (Euclidean) plane, the reviewer has recently encountered a striking instance of how imaginary figures may have essentially different properties from real figures. It is a standard theorem in elementary calculus that when one point approaches another on a curve the arc and the chord becomes ultimately equal, that is, the ratio of the arc to the chord approaches unity as its limit. This property of real analytic curves is true of most imaginary curves, as can be verified by calculation, but not of all. In the simplest class of exceptional imaginary curves, the limit is a certain irrational number, approximately .94. Thus the arc, instead of becoming equal to the chord, becomes *less* (of course in absolute value, since both arc and chord are complex quantities). Again, the statement is usually made that the difference between the arc and the chord is an infinitesimal of *third* order; but in the present instance it is in fact of the *first* order. The same class of curves shows

that even when there is no cusp or singular point the radius of curvature may vanish. It is remarkable that whenever the limit mentioned is not unity, it is at most equal to .94. For space curves the result is quite different, since the limit may then be any number, real or imaginary.²

The moral of all this is that if, originally, imaginaries were introduced into geometry because they made the statement of propositions, especially of algebraic geometry, *easier*, and bore out the principle of continuity, we have to pay for this nowadays by a systematic treatment of the imaginary figures in complete generality. We must look, with an enlightened view, over the entire complex domain, instead of restricting our attention, from some more or less accidental motive, to some cross section connected, more or less closely, with the original real domain. Of course there will always be justification for a purely real geometry (as instanced say by analysis situs, or the geometry of connection, including the theory of knots); but differential geometry has been guided mainly by the theory of analytic functions (power series), rather than the theory of functions of a real variable, and the tendency toward a perfect correspondence with the former theory seems all-compelling. The present period is one of transition, and that is always hard on both the writer of text-books and his students.

The author has certainly succeeded in getting into one volume most of the more important standard topics. This is shown by the chapter headings: Curves in space, General theory of surfaces, Organic curves of a surface, Lines of curvature, Geodesics, General curves on a surface and differential invariants, Comparison of surfaces, Minimal surfaces, Surfaces with plane or spherical lines of curvature and Weingarten surfaces, Deformation of surfaces, Triply-orthogonal systems of surfaces, Congruences of curves.

The treatment of each of these topics is quite elaborate, in many instances the proofs are more elegant than those usually given, and an abundant selection of problems (many

² See *Bull. Amer. Math. Soc.*, Vol. 20, p. 727.

of them difficult, and often containing important results, as is to be expected of a Cambridge treatise) is included.

Perhaps the most important and interesting feature of the book is the long chapter dealing with differential invariants, covariants, and parameters. The algebraic method employed is due to Forsyth himself, and was first published in a memoir in the *Philosophical Transactions*, 1903. The calculations are arranged very ingeniously, and the detailed results are certainly useful. The geometric interpretations, however, are not always clear, and sometimes they appear to be only partly geometric. The practise of calling a result geometric when it is in fact semi-geometric and semi-algebraic is unfortunately rather prevalent.

The author's terminology, in this connection, can not be recommended. He speaks of the invariants of "a single curve," when he really means a *system* of curves, simply infinite in number. His results have in fact no meaning for a single curve. It would be absurd to imply that the author's ideas are not clear—it is merely a matter of careless terminology. The distinction between a *system* of curves and a *curve* is just as great as that between a *curve* and a *point*. Of course a system is made up of an infinitude of curves, just as a curve is made up of an infinitude of points, but that is no excuse for identifying the configurations.

The long list of invariants for "two curves" refers actually to two simply infinite systems of curves, a figure usually called a *net* of curves. The author is not here discussing doubly-infinite systems. It is best to avoid the ambiguous term double system: it refers sometimes to a double infinity (that is, infinity times infinity) and sometimes to two single infinities (that is, a *net*).

After the discussion of "one curve" and "two curves," the rather mysterious statement is made that "we could not consider profitably more than two independent curves." As a matter of fact there are some very important (and naturally very difficult) problems connected especially with *three* systems, and, in

the reviewer's opinion, the investigation will have to be extended.

Another more serious confusion of terms, and even of ideas, is prevalent in geometric literature. We refer to the distinction between a *system* of curves and a *parametered system* of curves. The latter object arises frequently in applications. For example, in a topographic map we have to deal not merely with the system of contour lines, but with the particular numbers attached to these curves indicating the heights above sea level. The same system of curves with different numbers would represent a different topography. In most discussions in geometry we are concerned merely with the system of curves; but if the attached numbers or parameters are also of significance, as they often are, the compound object should be called not a system, but a parametered system.

Even in one dimension an analogous distinction is important. A curve consists of a single infinity of points: if the points are labeled with numbers, then we have a new figure, a *parametered curve*. A straight line with a logarithmic scale is certainly different from a straight line with an ordinary uniform scale. A correct and well developed terminology is at hand in, for example, d'Ocagne's *Nomography*. This branch of mathematics was originated and developed almost entirely by engineers (mainly the French school), rather than pure mathematicians, but it is certainly time for writers on geometry to take advantage of their work.

With this terminology, it is possible to state very compactly a fundamental theorem in the theory of functions of a complex variable, as follows: Any (analytic) parametered curve can be converted into any second parametered curve by a unique direct (and a unique reverse) conformal transformation. This is true of parametered curves but not of curves: any curve can be converted into a second curve by an infinitude of conformal transformations.

The author is to be commended for not confining himself, as much as most writers do, to questions of first and second order (of

geometric infinitesimals). Third order questions have been treated in a haphazard way in the standard literature. Even in the simple case of plane curves, the average student becomes familiar only with the interpretation of the first derivative as slope (tangent line), and of the second derivative as curvature (osculating curve). As regards the third derivative, his mind is usually blank. Even the elementary books should contain the definition of *deviation*, introduced by Transon over seventy years ago.

An excellent index and table of symbols will be appreciated by the student, and make the volume serviceable for convenient reference. The press work throughout is quite perfect.

EDWARD KASNER

COLUMBIA UNIVERSITY

A Catalogue of the Fishes of Japan. By DAVID STARR JORDAN, SHIGEO TANAKA and JOHN OTTERBEIN SNYDER. Journal of the College of Science, Tokyo Imperial University, Vol. XXXIII., article 1. Tokyo, 1913. 8vo. Pp. 1-497, with 396 text-figures.

Japan possesses a wonderfully rich fish fauna. This is due to several causes: first, to the fact that she consists of a chain of islands with innumerable small, sheltered bodies of water which afford great variety of depth, physical condition of sea floor, etc.,—factors highly favorably to a diversity of fish life. Secondly, to her remarkable north-and-south extent, which gives her in addition to the regular north temperate fauna, in itself unusually rich in this instance, a subtropical fauna allied to that of the Philippine Islands, in the south, and a fauna merging into a subarctic one, in the extreme north. Thirdly, her eastern coast is touched by the *Kuroshio*, or warm black current, which harbors many tropical forms, some of them exceedingly rare, or in fact, only known from this current.

With such remarkable conditions, it is not surprising that ichthyologists should have been attracted to the study of Japanese fishes. Many of the writers of this and the preceding generation have taken a hand in describing portions of this fauna as materials were

brought from Japan, so that an extensive literature has grown up about it. And there has been at least one extensive work on this fauna—that of Temminck and Schlegel, in two superb folio volumes, one of text and one of plates, published between 1842 and 1850.

But an entirely new chapter in Japanese ichthyology was opened when, in 1900, Chancellor Jordan and Professor Snyder, of Leland Stanford University, visited Japan for the purpose of studying the fishes. As a result of the collections then made, and of others made subsequently, including one by Gilbert and Snyder in the *Albatross*, in 1906, Jordan and his associates Gilbert, Snyder, Starks, Richardson, Fowler, Herre, Seale and Thompson, have worked unremittingly on this fauna, publishing paper after paper, until a long series, numbering several score, has now appeared. They have described hundreds of new species; figured, revised, re-studied, and thrown light on many of the darker problems relating to the fishes of Japan.

Early in the course of these studies it became patent to Jordan and Snyder that it was necessary to take stock of what had already been done on the Japanese fauna. Accordingly, in 1901, they published "A preliminary check-list of the fishes of Japan." This incorporated all the data then available, including two lists published by Japanese ichthyologists. The number of species listed was 686, many, however, only doubtfully referred to Japan. And now we have a new catalogue of the fishes of Japan from the pen of Jordan, Tanaka and Snyder. An idea of the enormous wealth of the Japanese fish fauna, as well as of the great stride that has been made in its study in a little over a decade, is shown in the fact that the present catalogue lists no less than 1,236 species (including the 6 given in the Additions and Corrections, pp. 429-430), or nearly twice the number known in 1901.

The catalogue—or check-list, as it might more correctly have been termed—enumerates the families, genera and species of the fishes occurring in the waters of Japan. Under each species is given a reference to the first describer, and generally, to a reviser; together

with the geographical distribution and one or more local Japanese names. Nearly one third of the species—396, to be exact—are illustrated, the admirable figures which have appeared in the publications of Jordan and his associates being reproduced. An excellent index to genera, species and Japanese names, covering 64 pages, greatly enhances the usefulness of the work. (This index, by the way, contains a number of misspellings—for instance, of *Scapanorhynchus*, *Etmopterus*, etc.).

A critic might perhaps find fault with the retention of a few superseded names, such as *Mitsukurina* for *Scapanorhynchus*, when it has been fairly well established that the former is identical with the fossil sharks which have long been known under the latter name; or with the omission of certain desirable references, to show that *Zameus*—to mention but a few instances—is a synonym for *Scymnodon*, *Deania* a synonym for *Centrophorus*, *Etmopterus frontimaculatus* probably a synonym for the Mediterranean *Spinax pusillus*,¹ etc. But in answer to such criticisms it may be said that the present list was obviously intended as a mere stock-taking of all the species that have been proposed, to serve as a basis for future work on the fishes of Japan; that it was not the purpose of the authors to give complete synonymies; and that these matters will be dealt with in the revisions of the various groups now being published by Jordan and his associates in America, or in the monograph by Tanaka, which is appearing in part in Japan. Altogether the catalogue is carefully compiled, and will be invaluable to all students of the fishes of Japan.

The work was seen through the press by Dr. Shigeo Tanaka, lecturer in zoology in the Imperial University of Japan, and a co-author of the present work; and to him are due the thanks of all who will profit by this volume, for the great care he has exercised in guarding against typographical errors in the text.

L. HUSSAKOF

AMERICAN MUSEUM OF NATURAL HISTORY

¹ See C. Tate Regan, "A Synopsis of the Sharks of the Family Squalidae," *Ann. Mag. Nat. Hist.*, 8 ser., II., 1908, pp. 39-57.

Pflanzenmikrochemie. Ein Hilfsbuch beim mikrochemischen Studium pflanzlicher Objekte von Dr. O. TUNMANN, Privatdozent an der Universität Bern. Ein Bd., pp. 631, mit 137 Abbildungen im Text. Verlag von Gebrüder Borntraeger, Berlin. 1913. M. 18.50.

That of the writing of books there is no end is one of the few biblical quotations which even the average freshman in college will recognize. Moreover, the graduate student in science, when sent to the library for references, is apt to wish that there might be fewer books for him to consult. Yet it is with a peculiar delight that the phytochemist witnesses the renewed literary activity in his particular field of research. Synthetic chemistry had so completely overshadowed phytochemistry for a generation and more since the days of Kekulé's structural theories, that the phytochemist is once more beginning to feel that his particular aspect of chemical research is again coming to its own. With a general treatise such as that by Haas and Hill, with Staetter and Stoll on chlorophyll, and with the volume on a special method of phytochemical technique like the one before us, all within less than a twelve-month, this unusual productivity must certainly be regarded as the heyday of phytochemical literature.

The general part of Tunmann's tome is devoted to the technique of microchemical research as applied to plants and covers sixty-three pages. Of the special part sixty-six pages are devoted to inorganic chemistry. Hence the bulk of the volume is devoted to the organic microchemistry of plants.

Inasmuch as this is the first general survey of its kind since the "Botanische Mikro-technik" by Zimmermann made its appearance in 1892, one may gladly welcome an up-to-date treatise on this subject. Even the person who is not well acquainted with the work that has been done during the past few decades in this particular field, will be struck by the innumerable references to special "Arbeiten" with which the pages abound. The pharmacist in particular will be gratified

to see to what extent the pharmacognosist and pharmaceutical chemists have contributed to make the microchemistry of plants an important branch of phytochemical investigation, pure as well as applied.

It ought to be possible in the future to supplement the macrochemical investigation of plants in a manner that should prove productive of the very best results. If the microscope, supplemented by accessories and chemical reagents, is going to enable the phytochemist of the future to extend the macroscopic examination carried out on one or several species to all members of a genus or even family with a minimum of material and possibly of time, the boundaries of plant chemistry ought to be extended farther in a decade than they have been during a century.

E. K.

THE ORIGIN OF CLIMATIC CHANGES¹

THE discussion of meteorological observations shows clearly that climates undergo variations of short duration, but such records as the presence of old lake beaches and the existence of well-marked glacial moraines, and other geological evidence distinctly point to climate changes covering long intervals of time. The evidence is not sufficient to characterize the variations as periodic, but the ice ages are sufficient to point to times when the conditions reached were extreme.

What may reasonably be assumed to be the chief established facts about such extensive changes may be summed up briefly as follows: Climatic changes were several, and probably many. Similar simultaneous changes occurred over the whole earth, or, in other words, it was warmer or colder over the whole earth simultaneously. These times of warmth or coldness were unequal in intensity and duration, and of irregular occurrence, and, lastly, they have taken place from very early, if not from the earliest geological age down to the present. Numerous theories, both probable and improbable, have been suggested from time to time to account for the origin of such

world-wide changes, and while each has its advocates, perhaps only three may be said to claim attention to-day. These may be briefly stated as the eccentricity theory (Croll), depending on the eccentricity of the earth's orbit; the carbon dioxide theory (Tyndall), based on the selective absorption and variation in amount of carbon dioxide; and thirdly, the solar variation theory, on the assumption of solar changes of long duration. A new theory, which may be called "the volcanic dust and solar variation theory," has recently been put forward by Professor W. J. Humphreys,² under the guarded heading, "Volcanic Dust and Other Factors in the Production of Climatic Changes, and Their Possible Relation to Ice Ages."

The author carefully points out that the idea that volcanic dust may be an important factor in the production of climatic changes is not new, but "though just how it can be so apparently has not been explained, nor has the idea been specifically supported by direct observation." He remarks also that while the pioneers regarded the presence of volcanic dust in the atmosphere as an absorbent of radiation, and so lowered the earth's temperature, modern observation suggests the opposite effect, namely, the warming of the earth's surface.

In putting forward his views of the action of dust, Professor Humphreys proceeds first to indicate that the dust that is effective is that which is situated in the atmosphere in the isothermal region or stratosphere. He then enters into the question of the size of the particles and probable time of fall, and concludes that particles of the size of 1.85 microns in diameter would take from one to three years to get back to the earth if they originally had been thrown up by a volcanic eruption.

Considering next the action of the finest and therefore most persistent dust on solar radiation, he finds that the "interception of outgoing radiation is wholly negligible in com-

² *Journal of the Franklin Institute*, August, 1913, Vol. CLXXVI., No. 2, p. 131; also *Bulletin of the Mount Weather Observatory*, August, 1913, Vol. VI., Part 1, p. 1.

¹ From *Nature*.

parison with the interception of incoming solar radiation."

Professor Humphreys now turns his attention to the observational evidence of pyrheliometric records, such readings being functions of, among other things, both the solar atmosphere and the terrestrial atmosphere. He thus introduces a curve showing smoothed values of the annual average pyrheliometric values, and compares this with sun-spot frequency values (representing solar atmospheric changes) and number of volcanic eruptions (representing terrestrial atmospheric changes). The similarity of the last-mentioned with the pyrheliometric curve leads him to write as follows: "Hence it appears that the dust in our own atmosphere, and not the condition of the sun, is the controlling factor in determining the magnitudes and times of occurrence of great and abrupt changes of insolation intensity at the surface of the earth."

The action of the dust intercepting at times as much as one fifth of the direct solar radiation leads him to inspect earth surface temperature values to inquire whether they are below normal on such occasions. The pyrheliometric and temperature curves suggest a relationship, but, as he states, "the agreement is so far from perfect as to force the conclusion that the pyrheliograph values constitute only one factor in the determination of world temperatures." A better agreement is secured when the combined effect of insolation intensity and sun-spot influence is considered.

The author then discusses the temperature variations since 1750 as influenced by sun-spots and volcanic eruptions, and indicates that the disagreement in the curves of temperatures and sun-spots is in every important instance simultaneous with violent volcanic eruptions.

Limitations of space will not permit us to remark on his references to the action of carbon dioxide in slightly decreasing the temperature or to probable great changes in level. Enough perhaps has been said to show that Professor Humphreys, in his interesting attempt to show "that volcanic dust must have been a factor, possibly a very important one,

in the production of many, perhaps all, past climatic changes . . .," has restated a topic which will no doubt call for criticisms and discussions from many quarters.

SPECIAL ARTICLES

THE EFFECT OF COLD UPON THE LARVÆ OF *TRICHINELLA SPIRALIS*

In the course of an investigation relative to *Trichinella spiralis*, it has been determined that cold has a decided destructive effect upon the encysted larvæ of this parasite. Heretofore it has been accepted as an established fact, upon the basis, however, of insufficient evidence, that low temperatures have no considerable influence upon the vitality of the larvæ of *Trichinella*. Although the results of only a single series of the writer's experiments are available at present, these results have been so definite that there can be little doubt as to the lethal action of cold upon *Trichinella* larvæ. The writer's experimental work thus far has shown that most of the parasites survive when exposed for as long as six days to a temperature ranging between 11° and 15° F. (—11.70° to —9.4° C.). On the other hand, when exposed to a temperature in the neighborhood of 0° F. (—17.8° C.) the larvæ of *Trichinella* quickly succumb. Only one out of over 1,000 larvæ examined has been found to survive an exposure of six days to this temperature. This was one among 275 isolated from a piece of trichinous meat which had been kept at a temperature of about 0° F. from September 27 to 30, allowed to thaw, and then again kept at the same low temperature, October 1 to 4, a total of six days' exposure. None was found alive among 498 larvæ from a piece of trichinous meat kept at about 0° F. September 27 to 30, allowed to thaw, then exposed again to the same low temperature October 1 to 3, and thus exposed five days in all, nor was any found alive among 233 larvæ from a piece of trichinous meat kept continuously at about 0° F. for five days. Out of 301 larvæ from trichinous meat kept at about 0° F. for three days only 5 showed signs of life. 225 out of 366 larvæ exposed for two days to a

temperature of about 0° F. were dead, and many of the remaining 141 showed only faint signs of life.

Results similar to the above were obtained from tests of trichinosed meat on guinea-pigs. Guinea-pigs fed with infested meat after its exposure to a temperature of about 0° F. for two, three, six and seven days, respectively, showed no trichinæ when killed and examined three weeks after feeding. A guinea-pig fed with meat from the same source which had been kept at a temperature of 11° to 15° F. for six days showed trichinæ when killed and examined three weeks after feeding.

It is evident that the results of these experiments, if confirmed by further investigation, are likely to be of great practical importance. Trichinosis in man is a very painful, frequently fatal, disease, and moreover it is comparatively common. Roughly estimated there have been recorded in the medical literature of this country about 1,200 cases of trichinosis, of which about 200 resulted in death. These figures undoubtedly include only a fraction of the cases which actually occur. Many cases of trichinosis recognized as such are not reported, and there is good reason to believe that the vast majority of cases are unrecognized, commonly passing as rheumatism, atypical typhoid fever, or as some other disease of uncertain nature. Some years ago Williams at Buffalo reported that he had found the parasite in 27 out of 505 cadavers examined for its presence, death in no instance having resulted from trichinosis. If Williams's findings be assumed to be statistically adequate, it may be concluded that five persons out of every 100 among the population typified by the 505 cadavers examined by him suffered from trichinosis at some time in their lives and recovered, in addition to which an indefinite number died of the disease. An extensive examination of cadavers throughout the United States would be required before general conclusions as to the prevalence of the parasite could be reached, but the numerous reported cases and Williams's figures are sufficient to prove that *Trichinella spiralis* is of common occurrence in man in this country. The prevalence of the

parasite in man of course depends upon its prevalence in hogs and the extent to which uncooked pork is used as food. The microscopic inspection of over 8,000,000 hogs in this country during a period of nine years showed that 1.41 per cent. were infested with living trichinæ, in addition to which there were 1.16 per cent. containing trichina-like bodies or disintegrating trichinæ, or a total of 2.57 per cent. The custom of eating raw pork is not unusual among the population of the United States as evidenced by the large quantities of various pork products intended to be eaten raw that are prepared by meat-packing establishments. Incidentally it may be noted that the consumption of such products seems to be increasing from year to year. In view of the frequent occurrence of trichinæ in hogs and the not altogether rare practise of eating raw pork it is not surprising that trichinosis should be a rather common disease in the United States. Inasmuch as warnings against the eating of raw pork seem to have little effect in discouraging this dangerous custom, certain countries in Europe have tried at great expense and not altogether successfully to guard the consumer by means of a system of microscopic inspection.

In this country microscopic inspection of all the hogs slaughtered under Federal supervision would require an expenditure of probably not less than \$5,000,000 per year over and above the sum already expended for federal meat inspection. Apart from other difficulties and objections of various sorts, the matter of expense alone is a serious difficulty in the way of a general trichina inspection, and as yet the federal government has not attempted such an inspection. In recent years, however, there has been some consideration of the question of a partial trichina inspection; that is, a microscopic inspection of those hogs slaughtered under federal supervision which are intended to be used in the manufacture of pork products of kinds customarily eaten raw. Such an inspection though it would by no means remove the danger, because even the best inspection is essentially imperfect, would greatly reduce the risk involved in the eating

of raw pork products, though, perhaps, on the other hand, it would tend to encourage the custom of eating raw pork among those persons who knew of the existence of a trichina inspection and of its purpose, and thus the good the inspection did in one way would be largely offset by the evil it did in another. The protection afforded by such an inspection would of course apply only to those pork products prepared under federal supervision and would not extend to products prepared in local establishments, or in private homes, even though the pork used came from animals slaughtered in inspected establishments, inasmuch as the special inspection for trichinæ would be given only to those hogs which were expressly intended to be used in the preparation of products of kinds customarily eaten raw. Nor would such an inspection afford any protection from the danger of contracting trichinosis through imperfectly cooked pork, as hogs not intended to be manufactured into products customarily eaten raw would not be inspected for trichinæ. The partial inspection in question, however, would cover the class of pork which seems particularly likely to be the most fertile source of trichinosis in so far as meats originating from establishments under federal inspection are concerned, and the consumer of raw pork products would thus be protected in large measure so long as he limited himself to those products specially labeled as inspected for trichinæ.

The results of the experiments recorded in this article naturally suggest the possibility of substituting refrigeration for microscopic inspection as a prophylactic measure. It is perhaps rather venturesome to express an opinion at the present time as to the extent to which refrigeration might be used practically as a preventive of trichinosis, but, if it be granted that it is desirable to institute measures which will serve to protect the consumer of raw pork products, leaving out of consideration the question of a general microscopic inspection of all hogs slaughtered, it seems to the writer, in view of the defects inherent in microscopic inspection even at its best, that refrigeration (provided the data at

present in hand are confirmed by further investigation) promises to afford a means of preventing trichinosis of far greater certainty, easier to apply, and less expensive than any method of trichina inspection yet devised. Instead of a microscopic inspection of the hogs from which raw pork products were to be prepared there would be required simply the refrigeration of the pork at a certain temperature for a certain length of time. It is possible, considering that the refrigeration of foods is becoming more and more general, keeping pace with the development of improved and more economical methods, that sooner or later the general refrigeration of pork, without reference to whether it is to be eaten raw or cooked, may become desirable and feasible as a prophylactic measure against trichinosis. For the present, however, it is probable that the use of refrigeration for this purpose is likely to have only a more limited application such as that which has been suggested, leaving for future development its possible further extension, all of which is of course contingent primarily upon the confirmation of the results of the experimental work recorded in this paper, and secondarily upon various other things, such as the effects of refrigeration upon the meat and the expense involved in the artificial production of cold.

Further investigation of this interesting question of the effect of cold upon trichinæ is in progress, and it is hoped that conclusive data as to the exact temperatures and time required to render trichinous meat innocuous will be available at an early date.

THE AMERICAN PHYSIOLOGICAL SOCIETY

THE 26th annual meeting of the American Physiological Society was held at the University of Pennsylvania and at the Jefferson Medical School, Philadelphia, December 28-31, 1913. One hundred and eighteen of the members of the society were present at the meeting. This, I think, was

the largest attendance in the history of the society. This large attendance was due, in part, to the fact that the societies representing the biochemists, the pharmacologists, the experimental pathologists, the anatomists, the zoologists and the naturalists met in Philadelphia at the same time. This is a most excellent plan, and should be made a fixed policy of the biological societies. The members of all the biological societies had joint dinners and smokers the three evenings of the meeting.

Two of the scientific sessions of the Physiological Society were joint meetings with the Biochemical and the Pharmacological societies. The scientific program was as usual a lengthy one and comprised a number of papers of unusual importance. The number and general high grade of the demonstrations was also a feature of the meeting. The following is a list of the scientific communications:

"Phlorhizin Glycosuria before and after Thyroidectomy," by Graham Lusk.

"Studies in Diabetes: (1) The Effect of Different Compounds on Glycogenesis; (2) The Mechanism of Antiketogenesis," by A. I. Ringer and E. M. Fraenkel.

"Some Problems of Growth: (a) The Capacity to Grow; (b) The Role of Amino Acids in Growth," by L. B. Mendel and T. B. Osborne.

"Further Studies in the Comparative Biochemistry of Purine Metabolism," by Andrew Hunter.

"Changes in Fats during Absorption," by W. R. Bloor.

"Immunization Against the Anti-coagulating Effect of Leech Extract," by Leo Loeb.

"Anaphylaxis in the Cat and Opossum," by C. W. Edmunds.

"Vividiffusion: Report on Preliminary Results," by J. J. Abel, L. S. Rowntree and B. B. Turner.

"A Method of Dialyzing Normal Circulating Blood and Some of Its Applications," by C. L. V. Hess and H. McGuigan.

"A Biological Test for Iodin in the Blood," by A. Woelfel and A. L. Tatum.

"Further Studies of the Excretion of Acids," by L. G. Henderson and W. W. Palmer.

"Studies on Blood Plates," by T. F. Zucker.

"The Condition of the Blood in Hemophilia," by W. H. Howell.

"Some Physiological Factors Affecting the Coagulation Time of Blood," by W. B. Cannon and W. L. Mendenhall.

"The Action of Epinephrin on the Heart," by J. A. E. Eyster.

"Two Types of Reflex Fall of Blood Pressure," by P. G. Stiles and E. G. Martin.

"Dierotism and the Brachial Flow Pulse (with lantern demonstrations)," by A. W. Hewlett.

"The Periodic Cardio-vascular and Temperature Variations in Women," by Jessie L. King.

"Acceleration of the Heart in Exercise," by H. S. Gasser and W. J. Meek.

"On the Constancy of Blood Pressure and Vaso-motor Reactions in the Anesthetized Dog," by R. G. Hoskins and H. Wheelon.

"The Relative Systolic Discharge of the Left and the Right Ventricles," by A. L. Prince.

"The Effect of Vagal Stimulation on the Location of the Pacemaker of the Mammalian Heart," by W. J. Meek and J. A. E. Eyster.

"The Effect of Pulsation on Filtration," by R. A. Gesell.

"The Action of Pilocarpin on the Cerebrospinal Fluid," by F. C. Becht.

"The Osmotic Properties of Clam's Muscle," by E. B. Meigs.

(a) "Sources of Surface Tension in Striated Muscle," (b) "Maximum Surface Tension in Striated Muscle," by W. N. Berg.

"Some Characteristics of Mammalian Muscle," by F. S. Lee.

"Some Results Obtained by the Use of Quantitative Faradic Stimuli in Physiological Investigation," by E. G. Martin.

"Faradic Stimuli: A Physical and Physiological Study," by J. Erlanger and W. E. Garrey.

(a) "The Metabolic Gradient in the Nerve Fiber," (b) "The Action of Anesthetics on the CO₂ Production in the Nerve Fiber," by S. Tashiro.

"Proof that the Propagation of the Nervous Impulse Obeys the Laws of Propagation of Electricity along Conductors with Distributed Capacity," by A. C. Crehore and H. B. Williams.

"Saline Perfusion of the Spinal Centers in Frogs: The Effect of Calcium and Potassium Chloride," by R. D. Hooker and S. O. Reese.

"Variations in the Reflex Responses through Medullary Centers," by H. C. Jackson and E. M. Ewing.

"Evidences in the Cerebral Cortex of Mental Equipment and Intellectual Development," by E. L. Mellus.

"The Influence of Surroundings on Foveal Vision," by P. W. Cobb.

"The Effect of Strychnin on Reflex Thresholds," by E. L. Porter.

"The Influence of the Vagi on Renal Secretion," by R. G. Pearce.

"Stimulation of the Semi-circular Canals," by F. H. Pike.

"Demonstration of Vividiffusion," by J. J. Abel, L. G. Rowntree and B. B. Turner.

"The Determination of Blood Sugar," by P. A. Shaffer.

"Intestinal Peristalsis in *Homarus*," by F. R. Miller.

"Methods for Studying the Pharmacology of the Circulation," by C. Brooks.

"The Contour of the Intraventricular and the Pulmonary Arterial Pressure Curves by two new Optically Recording Manometers," by C. J. Wiggers.

"Some Time-saving Laboratory Methods," by C. C. Guthrie.

"A Graphic Method for Recording the Coagulation of Blood," by W. B. Cannon and W. L. Mendenhall.

"Some Mutual Relations of Oxalates, Salts of Magnesium and Calcium: Their Concurrent and Antagonistic Actions," by F. L. Gates and S. J. Meltzer.

"A Method of Obtaining Successive Contrast of the Sensations of Hunger and Appetite," by A. J. Carlson.

"Further Observations on the Pyramidal Tracts of the Raccoon and Porcupine," by S. Simpson.

"A New Apparatus for Demonstration of the Dioptries of the Eye and the Principles of Ophthalmoscopy and Retinoscopy," by A. Woelfel.

"Simple Experiments on Respiration for the Use of Students," by Y. Henderson.

"Convenient Modification for Venous Pressure Determinations in Man," by R. D. Hooker.

"Device for Interrupting a Continuous Blast of Air. Designed Especially for Artificial Respiration," by R. A. Gesell and J. Erlanger.

"A Simple Liver Plethysmograph," by C. W. Edmonds.

"An Artificial Circulation Apparatus for Students," by W. P. Lombard.

"A Simplified and Inexpensive Oxadase Apparatus," by H. H. Bunzel.

"An Improved Form of Apparatus for Perfusion of the Excised Mammalian Heart," by M. Dresbach.

"Sugar Consumption in Eviscerated Animals," by J. J. R. Macleod and R. G. Pearce.

"On the Rapid Disappearance from the Blood of Large Quantities of Dextrose Injected Intravenously," by I. S. Kleiner and S. J. Meltzer.

"Further Observations on the Metabolism of Depancreatized Dogs," by J. R. Murlin.

"Transfusion of Blood in Severe Diabetes Mellitus," by R. T. Woodruff and B. O. Raulston.

"The Cause of Diabetic Polyphagia," by A. B. Luckhardt.

"Preliminary Report on Work with a Respiration Calorimeter in Bellevue Hospital," by E. F. DuBois.

"The Role of Nascent Oxygen in Protecting the Body from Self-digestion," by W. E. Burge.

"The Effect of Castration on the Hypophysis in the Rabbit," by A. E. Livingston.

"The Secretion of Gastric Juice during Parathyroid Tetany," by R. W. Keeton.

"The Brain-Adrenal-Thyroid-Liver-Pancreas Syndrome (Kinetic System)," by G. W. Crile.

"The Variations in the Hunger Contractions of the Empty Stomach with Age," by T. L. Patterson.

"The Control of the Hunger Mechanism," by A. J. Carlson.

The following persons were elected to membership in the society: E. F. DuBois, Cornell University Medical School; O. C. Glaser, University of Michigan; E. M. Ewing, Bellevue Medical School; S. Tashiro, University of Chicago; A. L. Tatum, University of Chicago; H. Laurens, Yale University; J. E. Sweet, University of Pennsylvania; E. Lodholz, University of Pennsylvania; G. Fahr, Johns Hopkins Medical School; J. H. King, Johns Hopkins Medical School; R. E. Gesell, Washington University, St. Louis; O. O. Stoland, University of South Dakota; E. L. Porter, Harvard Medical

School; P. E. Howe, Columbia University; H. A. Mattill, University of Utah; Mabel P. FitzGerald, New York City.

This makes the total membership of the society 210.

The most important matter in the way of business was the ratification of the work of the conference committee appointed at the Cleveland meeting establishing the Federation of American Societies for Experimental Biology. One of the aims of this federation is the coordination of the scientific work of the annual meetings, a successful beginning of which was made this year. But a great deal of the credit for this successful beginning is due to the splendid facilities offered by the Philadelphia institutions, and the careful planning and hard work of the local committee.

The Washington University presented an invitation to meet in St. Louis next year. The society voted in favor of meeting in St. Louis, but the final decision is left with the executive committee of the federation.

The editorial committee (Drs. Porter, Carlson, Erlanger, Howell, Lee, Lusk, Macallum) was instructed by the society to report at the next annual meeting on the relation of the *American Journal of Physiology* to the American Physiological Society and to propose measures to improve the facilities for publication on the part of American physiologists.

Officers for the year 1914.—President, W. B. Cannon; Secretary, A. J. Carlson; Treasurer, J. Erlanger; Members of the Council, F. S. Lee, S. J. Meltzer.

A. J. CARLSON,
Secretary

UNIVERSITY OF CHICAGO,
January 10, 1914

THE AMERICAN PHYTOPATHOLOGICAL SOCIETY

The society met in affiliation with the American Association for the Advancement of Science in the state capitol at Atlanta, Ga., December 30, 1913, to January 2, 1914.

The following officers were elected:

President, Dr. Haven Metcalf, U. S. Department of Agriculture, Washington, D. C.

Vice-president, Dr. Frank D. Kern, Pennsylvania State Agricultural Experiment Station, State College, Pa.

Member of Council, Dr. H. R. Fulton, North Carolina Agricultural Experiment Station, West Raleigh, N. C.

Chief editors of *Phytopathology* were elected as follows: Dr. L. R. Jones, for one year; Dr. C. L.

Shear, for two years; Dr. R. A. Harper, for three years.

The following associate editors were elected for three years: Dr. F. D. Heald, Dr. Mel T. Cook, Dr. B. M. Duggar, Professor F. C. Stewart.

Dr. Donald Reddick was reelected business manager of *Phytopathology*.

About fifty members were in attendance.

The society decided to hold its next meeting in conjunction with the American Association for the Advancement of Science at Philadelphia, Pa.

The following program was presented by abstract, the abstracts having been published and distributed before the meeting. This plan was undertaken in an attempt to devise some means of securing time to discuss the numerous papers which are offered for presentation. These abstracts were read by the authors and formed the basis of questions and discussions. The plan was generally pronounced a great success, as it resulted in rather a full discussion of almost every paper presented.

"Fruit Rots of Egg Plant," by Frederick A. Wolf.

"Formaldehyde Gas Injury to Potato Tubers," by F. C. Stewart and W. O. Gloyer.

"Stem Rot and Leaf Spot of *Clematis*," by W. O. Gloyer.

"A Preliminary Note on the Cause of 'Pecky' Cypress," by W. H. Long.

"Inspection and Certification of Potato Seed Stock," by W. A. Orton.

"The Fungus Genus *Verticillium* in Its Relation to Plant Diseases," by W. A. Orton.

"A Phoma Rot of Irish Potatoes," by I. E. Melhus.

"A New Rust of Economic Importance Occurring on Pomaceous Hosts," by H. S. Jackson.

"Notes on the White Pine Blister Rust," by Perley Spaulding.

"Relation of the Mosaic of the Pepper and the Filiform Leaf of the Tomato to the Mosaic of the Tobacco," by Carl A. Schwarze.

"*Cladosporium* Disease of *Ampelopsis tricuspidatum*," by Mel. T. Cook and Guy West Wilson.

"The Use of Sulphur Lime Wash as a Remedy for Apple Scab," by R. Kent Beattie.

"Cotton Anthracnose. Some Field Problems and Some Field Experiments," by H. R. Fulton, J. R. Winston and R. O. Cromwell.

"Can *Cronartium ribicola* Overwinter on the Currant," by F. C. Stewart and W. H. Rankin.

"An Improved Method of Making Separation Cultures," by A. F. Blakeslee.

"Collar-blight of Apple Trees in Pennsylvania," by C. R. Orton and J. F. Adams.

"Fusaria of Potatoes," by C. D. Sherbakoff.

"Some Points in the Life History of *Phytophthora* on Ginseng," by J. Rosenbaum.

"Comparative Dusting and Spraying Experiments," by F. M. Blodgett.

"*Sphaeropsis* Canker of *Quercus prinus*," by W. H. Rankin.

"Biological Strains of *Sphaeropsis malorum*," by L. R. Hesler.

"Decay of Celery in Storage," by D. Reddick.

"A Destructive Nematode Introduced into the United States," by L. P. Byars.

"Experiments on the Control of Certain Barley Diseases," by A. G. Johnson.

"Some Observations and Experiments on the Black-leg of Cabbage," by M. P. Henderson. (With lantern.)

"The Non-validity of the Genus *Lasiodiplodia*," by J. J. Taubenhaus.

"Progress in Developing Disease Resistant Cabbage," by L. R. Jones. (With lantern.)

"Disease Resistance in Tobacco to Root Rot," by James Johnson. (With lantern.)

"The Life History of *Sphaeropsis malorum* Berk.," by C. L. Shear. (With lantern.)

"Blossom-end Rot of Tomato," by Charles Brooks. (With lantern.)

"A Little-known Disease of Chestnut and Oak Trees," by F. D. Heald. (With lantern.)

"A Preliminary Report on Fruit Infection of the Peach by Means of Inoculation with *Cladosporium carpophilum* Thum. from Peach Twigs," by G. W. Keitt. (With lantern.)

"Bibliographical Citations," by C. L. Shear.

"Some Recent Studies on New or Little-known Diseases of the Sweet Potato," by J. J. Taubenhaus. (With lantern.)

"Wind Dissemination of Ascospores of the Chestnut Blight Fungus," by F. D. Heald, M. W. Gardner and R. A. Studhalter. (With lantern.)

"Longevity of Pycnospores of the Chestnut Blight Fungus in Soil," by M. W. Gardner.

"The Relation of Temperature to the Expulsion of Ascospores of *Endothia parasitica*," by R. C. Walton.

"Insects as Carriers of the Chestnut Blight Fungus," by R. A. Studhalter.

"Perithecia in Cultures of *Venturia inequalis*," by Fred R. Jones.

"Gum Formation in *Citrus* as Induced by Chemicals," by B. F. Floyd.

"A Study of the Annual Recurrence of *Phytophthora infestans*," by I. E. Melhus.

"Fungous Gummosis of *Citrus* in California,"

by H. S. Fawcett.

C. L. SHEAR,

Secretary-Treasurer

THE PALEONTOLOGICAL SOCIETY

THE fifth annual meeting of the Paleontological Society was held at Princeton, N. J., on Wednesday, December 31, 1913, and Thursday, January 1, 1914, in affiliation with the Geological Society of America. The meeting this year included a general session in which selected papers of interest to all members of the society were read, and special sessions dealing with vertebrate and invertebrate paleontology and paleobotany. Notable features of the meeting were first, the president's address by Dr. Charles D. Walcott on the Cambrian of western North America, and second a conference on the close of the Cretaceous and opening of Eocene time. In the latter the geological and paleontological evidence was presented by Messrs. F. H. Knowlton and T. W. Stanton, and recent discoveries in regard to late Cretaceous and early Eocene life were reported especially as a result of the American Museum expeditions under Messrs. Barnum Brown and Walter Granger.

A new Ungulate of very distinctive South American type was recorded by Dr. Matthew as additional evidence of affinity between North and South America in Lower Eocene times. The line of ancestry of the Uintatheres was recorded as traced into Basal or Paleocene times. A new fauna is described between the Puero-Torrejon and Wasatch, to be known as the Clark Fork. Still more striking was the record of Mr. J. W. Gidley, of the U. S. National Museum, of the occurrence of a true eland *Taurotragus* in the Pleistocene cave of western Maryland. This discovery confirms the statement of J. C. Merriam of the occurrence of African antelopes in Virgin Valley, northern Nevada and links North America very closely to Asia in Pliocene times. Accompanying the eland was a peculiar species of African dog.

R. S. BASSLER,

Secretary

SOCIETIES AND ACADEMIES

THE BIOLOGICAL SOCIETY OF WASHINGTON

THE 516th meeting of the society was held on November 15, 1913, Vice-president Paul Bartsch in the chair and 35 persons present.

F. V. Coville presented a communication on

"The Physiology of the Blueberry." His remarks were based on wide experience in greenhouse and outdoor culture of this plant. Three conditions are essential to its successful propagation: first, an acid soil; second, the presence of the micorrhizal fungus to enable the plant to obtain nitrogen, and third, the stimulating effect of cold on the twigs while they are dormant. The last is a condition of vital importance, associated as it is with the transformation of starch into sugar. As a result of this series of experiments, the commercial propagation of the blueberry is now possible. Very large berries have been developed, some of them from $\frac{1}{2}$ inch to $\frac{3}{4}$ inch in diameter. The various means of cultivation were explained and illustrated by means of numerous lantern slides.

W. C. Kendall, the second speaker announced on the program, was absent, and the chairman asked Dr. Leon J. Cole, of the University of Wisconsin, to address the society. He responded by giving an account of his experiments in breeding pigeons for the study of color inheritance.

Owing to lateness, the communication by Barton W. Evermann was postponed.

THE 517th meeting of the society was held on November 29, 1913, President E. W. Nelson in the chair and 63 persons present.

The meeting was devoted to a discussion of Parallel Development. A. D. Hopkins read a paper on "Parallelism in Morphological Characters and Physiological Characteristics in Scolytoid Beetles." He had made a special study of these beetles and his ideas of parallelism in nature were largely founded on evidence they have furnished. He defined the subject as follows:

"Parallelism in morphological characters and physiological characteristics in Scolytoid beetles relates to the occurrence of the same or similar elements of structure or the same kind of activity in two or more species, genera, subfamilies or families. Parallel species, genera and larger groups are those in which structure or habit is in many respects alike. Such species or groups may be closely allied or more or less widely separated. Universal parallelism relates to repeated or multiple origin, development and evolution of the same or similar inorganic or organic form or activity.

"This tendency towards parallel development appears to be in accordance with a fundamental principle or law of *parallelism in evolution*, under which the origin and evolution of the same form or activity, under the same or similar physical in-

fluences, has been repeated many times; or, in other words, that under similar environments, needs, and requirements in nature, independent development and evolution from a common base may produce repeatedly the same or similar morphological and physiological results."

Numerous examples were given and illustrated on the board, of characters of structures and characteristics of habit which were paralleled over and over again in connected and disconnected genera, subfamilies and families. He also illustrated characters and characteristics which were paralleled in all of the species of a single genus and in connected genera, groups, subfamilies and families, and said further:

"Thus we see that parallel modification in morphological and physiological elements is an important factor to be considered in taxonomy. It is evident from a comparative study of the various systems of classification that the failure of taxonomists to fully realize its importance has led to many erroneous conclusions and much confusion.

"In conclusion, it seems to me that we have two fundamental questions to be answered in regard to the origin, evolution and classification of organisms:

"1. Are the taxonomic characters and characteristics of the species, genus, family, order, class and kingdom, the result of *phylogenetic descent from a single ancestral nucleus, through natural selection and the inheritance of selected characters?* or

"2. Are they the result of *phylogenetic descent from many nuclei through natural selection and natural parallelism?*

"I am inclined to the belief that an affirmative answer to the second question would be more nearly in accordance with natural law.

"Phylogenetic descent from a single source is represented by a single genealogical tree.

"Parallelism from different sources may be represented by a forest of genealogical trees, the different elements of which are as near alike as the branches, leaves, flowers and fruit of a forest of oak trees."

President Nelson exhibited a series of mammals similar in outward appearance but widely different in structure and classification, showing the parallelism of shape and color.

H. C. Oberholser discussed parallel development as illustrated in birds. He showed a large series of specimens in which resemblances in form and color were very striking.

J. W. Gidley pointed out the difference between parallel and convergent development.

Messrs. Lyon, Hay, Baker, Bartsch and Gill took further part in the discussion.

In closing, Dr. Hopkins remarked on the large number and most striking examples of parallelism in the mammals and birds which had been exhibited by Messrs. Nelson and Oberholser, stating that the discussion based on them had related to only one phase of the principle, namely, disconnected or homomorphic parallelism which was very different from related or homologous parallelism. One is parallelism in structure, color, habit, etc., which is not correlated with evidences of natural affinity, but is repeated in more or less widely separated groups and species, while the other is parallelism of structure, color, habit, etc., which is correlated with evidences of natural affinity and is repeated in the same species or in connected genera or larger groups.

We must not overlook the fact that there are many different kinds of parallel modifications in evolution, some applying to the universe in the parallel development of systems, suns and planets, others to chemical elements and compounds, others to psychological phenomena, etc. Indeed, its manifestation in all branches of human knowledge is so evident that it may be considered as representing a science.

THE 34th annual meeting and 518th regular meeting of the society was held on December 13, 1913, President E. W. Nelson in the chair and 28 persons present.

The annual reports of the officers were read.

The election of officers for the year 1914 resulted as follows:

President: Paul Bartsch.

Vice-presidents: J. N. Rose, A. D. Hopkins, W. P. Hay, Mary J. Rathbun.

Recording Secretary: D. E. Lantz.

Corresponding Secretary: W. L. McAtee.

Treasurer: Wells W. Cooke.

Members of Council: William Palmer, Hugh M. Smith, Vernon Bailey, Marcus W. Lyon, Jr., N. Hollister.

The president, Paul Bartsch, was selected to represent the society as vice-president in the Washington Academy of Sciences.

President Bartsch appointed the following committee on publication: N. Hollister, W. L. McAtee, Wells W. Cooke.

D. E. LANTZ,
Recording Secretary

Stanford University MEDICAL SCHOOL

The Medical School of the Leland Stanford Jr. University is an integral part of the University and its Faculty controls the Lane Hospital which together with the Lane Medical Library is administered by the Trustees of the University.

ADMISSION

Three years of University instruction including a year in Physics, Chemistry and Biology with laboratory work in each and a satisfactory reading knowledge of French or German are required for admission to candidacy for the degree of Doctor of Medicine.

INSTRUCTION

The work in Medicine begins the first of September each year and closes about the middle of May. The first year and a half of the four years' Medical instruction is given in the laboratories at Stanford University, California, near Palo Alto, and the last two and a half years in the buildings of the Medical School in San Francisco, Calif. The degree of A.B. is granted upon completion of the first year of the Medical Curriculum. Students entering September 1914 or thereafter will be required to spend an additional interne or practical year before receiving the degree of M.D.

TUITION

The tuition is \$150 per year, payable in two installments, September and January.

The annual announcement of the Medical School or annual Register of the University will be sent upon application to

THE DEAN OF THE

Stanford University Medical School

Sacramento and Webster Sts.

San Francisco, Calif.

Laboratory Apparatus

MADE BY

SIEMENS & HALSKE

Siemens and Halske manufacture an excellent line of Laboratory Apparatus, including Precision Electrical Measuring Instruments (Voltmeters, Ammeters, Wattmeters, Frequency Meters, and Transformers), Oscillographs, Iron Testing Apparatus, Resistance Boxes, Bridges, Induction Standards, Potentiometers, High Frequency Machines, Galvanometers, etc.

Catalog 56 (1912 Edition) contains 200 pages of descriptive matter, handsomely illustrated. Write for a copy today.

Saunders' Books

Brill's Psychanalysis

APPLICATION OF
FREUD'S THEORIES

This one volume gives you the practical application of all Freud's theories, and it gives it to you from the pen of a man thoroughly competent to write on this subject. Psychanalysis is the only system of psychotherapy which deals with the neuroses as *entities* instead of treating symptoms, as do hypnotism, suggestion, and persuasion. The results of psychanalysis are most effective. It is only through psychanalysis you can gain a real insight into the neuroses and psychoses. You will find Brill's work most valuable.

Octavo of 337 pages. By A. A. BRILL, Ph.B., M.D., Clinical Assistant in Psychiatry and Neurology at Columbia University Medical School. Cloth, \$3.00 net.

Daugherty's Economic Zoology

This work is issued, for convenience, in two parts. Part I is a *Field and Laboratory Guide*, interleaved for notes. Part II is the textbook part or the *Principles*. Not only does this work give the salient facts of structural zoology and the development of the various branches of animals, but also the natural history—the *life and habits*—thus showing the interrelations of structure, habit and environment.

Part I—*Field and Laboratory Guide*: 12mo of 275 pages, interleaved. Cloth, \$1.25 net. Part II—*Principles*: 12mo of 406 pages, illustrated. Cloth, \$2.00 net. By L. S. DAUGHERTY, M.S., Ph.D., Professor of Zoology, State Normal School, Kirksville, Mo.; and M. C. DAUGHERTY, author with Jackson of "Agriculture Through the Laboratory and School Garden."

Stiles' Nutritional Physiology

This new work expresses the most advanced views on this important subject. It discusses in a concise way the processes of digestion and metabolism. The keyword of the book throughout is "energy"—its source and its conservation.

12mo of 295 pages, illustrated. By PERCY GOLDTHWAIT STILES, Assistant Professor of Physiology at Simmons College, Boston. Cloth, \$1.25 net.

STANSFIELD

 (NEW SECOND
EDITION)

The Electric Furnace

Now Ready

By ALFRED A. STANSFIELD, D.Sc. Birks Professor of Metallurgy in McGill University, Montreal. 415 pages, 6x9, 155 illustrations, \$4.00 (17s) net, postpaid.

Prof. Stansfield brings down to date the important facts relating to the theory and practice of the electric furnace.

The first edition of his book has been a standard. Since its publication in 1907, the development of the electric furnace and the increase in its use have been rapid.

The present edition is twice the size of the first—a growth made necessary both by the advance in the industry and the demand for more detailed treatment of the subject.

It covers not only the progress but the essential, practical features of design, operation and use. It is filled with valuable data, drawings and practical suggestions.

LYON

 (JANUARY,
1914)

Problems in Alternating Current Machinery

By WALDO V. LYON, Instructor in Electrical Engineering, Massachusetts Institute of Technology. 135 pages, 6x9, \$1.50 (6/3) net, postpaid.

A set of problems concerning the theory of the operation of alternating current machinery. There are 500 in all, grouped in seven sections, and arranged logically and in the approximate order of their difficulty. The usefulness of the book among classes of students is increased by the large variety, ranging from the very simple to those of considerable difficulty.

CALDWELL

 (JANUARY,
1914)

Electrical Engineering Problems

Part I. Direct Current Circuits and Apparatus.

Part II. Alternating Current Circuits and Apparatus.

By F. C. CALDWELL, Professor of Electrical Engineering at the Ohio State University. 105 pages, 6x9, \$1.00 (4/2) net, postpaid.

A collection of 612 class-room problems, classified in 30 groups, for college courses in direct and alternating current circuits and apparatus. A novel feature is the statement of time needed to perform the actual solving of each problem. It is suitable for use with any of the available textbooks or with a lecture course.

THE INTERNATIONAL
CHEMICAL SERIES
MAHIN

(Jan., 1914)

Quantitative Analysis

By EDWARD G. MAHIN, Associate Professor of Chemistry in Purdue University. 510 pages, 119 illustrations, \$3.00.

A book that is broader in scope than the usual text. It aims to produce in the mind of the student a clear comprehension of the scientific development of quantitative methods. It is especially valuable to the commercial chemist since it devotes nearly 250 pages to the latest methods of "Analysis of Industrial Products and Raw Materials."

CONTENTS

Chapter I.—General Principles. II.—Gravimetric Analysis. III.—Experimental Gravimetric Analysis. IV.—Electro-Analysis. V.—Volumetric Analysis. VI.—Color Change of Indicators. VII.—Standardization. VIII.—Experimental Volumetric Analysis. IX.—Oxidation and Reduction. X.—Titrations Involving the Formation of Precipitates. XI.—Analysis of Industrial Products and Raw Materials.

WHITE

(Sept., 1913)

Technical Gas and Fuel Analysis

By ALFRED H. WHITE, Professor of Chemical Engineering, University of Michigan. 255 pages, 47 illustrations, \$2.00.

LORD & DEMOREST (Sept., 1913)

Metallurgical Analysis

By NATHANIEL W. LORD, late Professor of Metallurgy. Revised by DANA J. DEMOREST, Professor of Metallurgy, Ohio State University. 327 pages, illustrated, \$2.50.

NORRIS

(Nov., 1912)

Organic Chemistry

By JAMES F. NORRIS, Professor of Chemistry, Simmons College, Boston, Mass. 566 pages, illustrated, \$2.50.

CADY

(Oct., 1912)

Inorganic Chemistry

By HAMILTON PERKINS CADY, Professor of Chemistry, University of Kansas. 606 pages, illustrated, \$2.50.

NATIONAL ACADEMIES AND THE PROGRESS OF RESEARCH¹

II. THE FIRST HALF CENTURY OF THE NATIONAL ACADEMY OF SCIENCES

In the days preceding the American Revolution, the Royal Society was to this country what it still is to the existing British Colonies: the central and authoritative representative of scientific research.² Americans eminent for their contributions to science were elected Fellows, and their papers appeared in the *Philosophical Transactions*. The list of colonial Fellows includes Cotton Mather, Bowdoin, Dudley, and the three Winthrops in New England; Franklin, Rittenhouse and Morgan in Pennsylvania; Banister, Clayton, Mitchell and Bird, in Virginia, and Garden and Williamson in the Carolinas. But sodistant a body could not meet all local needs. Thus Franklin, active in every field, undertook the organization of the American Philosophical Society in 1743, some years before its time, as its early demise proved. In 1766 the American Society held at Philadelphia for Promoting Useful Knowledge was established and Franklin, then in Europe, was elected its first president. In the meantime the earlier society was revived, and

¹ For most of the material in the following pages the writer is indebted to a history of the "First Half Century of the National Academy of Sciences," prepared and edited by Frederick W. True in connection with the recent celebration of the fiftieth anniversary of the founding of the academy.

² See an excellent article by G. Browne Goode, from which the data used in the introduction of the present paper are taken: "The Origin of the National Scientific and Educational Institutions of the United States," Annual Report of the American Historical Association for 1889.

the amalgamation of the two in 1769 gave rise to a scientific body which has always exercised a powerful and beneficent influence on the progress of science in the United States. The prominence in the affairs of state of its leading members is illustrated in the frequent interruptions to the proceedings of the society between 1773 and 1779, when these men, who included Washington, Franklin, Jefferson and Adams, were occupied with the labors of organizing the new republic. The American Philosophical Society, modelled after the Royal Society, but embracing the whole field of knowledge, soon assumed great importance at its seat in Philadelphia, then the center of American scientific and literary life.

John Adams, when representing the United States in France, learned of the appreciation in which the Philosophical Society was held in academic circles. On his return to Boston in 1779 he suggested the establishment of the American Academy of Arts and Sciences, which was duly incorporated by act of the Massachusetts State Legislature in 1780. At this time the influence of France was naturally more potent than that of England, and the Academies of Paris were chosen as models by the charter members of the new organization.

The year 1778 marks the inception of an ambitious plan, proposed by the Chevalier Quesnay de Beaurepaire. His scheme for the Academy of Arts and Sciences of the United States had been endorsed by the King of France, the Royal Academies of Science and of the Fine Arts, and by Lavoisier, Condorcet and many eminent Frenchmen. The sum of sixty thousand francs was subscribed by wealthy Virginians, and a building was erected in Richmond in 1786. One (French) professor was appointed to make natural history collections and extensive plans for branch

establishments in Baltimore, Philadelphia and New York were contemplated. But the French Revolution put an end to this intellectual exotic.

In the present paper, devoted primarily to the history of the National Academy, we must pass over many interesting developments in the early scientific life of the nation, some of which will be mentioned elsewhere. Reference must be made, however, to the incorporation of the American Association for the Advancement of Science in 1848, and the intense vitality which has enabled this body, in cooperation with many special societies of later origin, to bring the results of scientific research within the reach of an ever-widening public.

Alexander Dallas Bache, superintendent of the United States Coast Survey from 1843 to 1867, and one of the leading spirits of his time, was among the first to express publicly the demand for a national organization of American research officially recognized as such by Congress. In his presidential address to the American Association for the Advancement of Science in 1851 he emphasized the need of "an institution of science, supplementary to existing ones, to guide public action in reference to scientific matters."

Suppose an institute of which the members belong in turn to each of our widely scattered states, working at their places of residence and reporting their results; meeting only at particular times, and for special purposes; engaged in researches self-directed, or desired by the body, called for by congress or by the executive, who furnish the means for the inquiries. . . . The public treasury would be saved many times the support of such a council, by the sound advice which it would give in regard to various projects which are constantly forced upon their notice, and in regard to which they are compelled to decide without the knowledge which alone can ensure a wise conclusion.

. . . Such a body would supply a place not occupied by existing institutions, and which our own

is; from its temporary and voluntary character, not able to supply.³

As president of the American Association, and as a prominent member of the American Philosophical Society and the American Academy of Arts and Sciences, he entertained no misconception regarding the admirable aims and the no less admirable successes of these older societies. Each performed then, as it does now, a useful function of broad scope, which the proposed organization was not to rival but to supplement. The American Philosophical Society continues to exert a wide and useful influence, drawing to its annual meetings in Philadelphia a large body of able men, representing every field of knowledge. Its strong vitality and its traditions of a scholarly past are shared by the American Academy, now rapidly increasing in membership and advantageously established in the permanent home provided for it in Boston by Alexander Agassiz. The American Association, like the British Association for the Advancement of Science, holds its annual meetings in widely scattered cities, thus bringing under its influence a great number of people, whose attention might not be attracted from a distance. Clearly there was still room for an academy chartered by congress and closely related to the national government, to which it might render some such services as the principal countries of Europe receive from their great academies.

Bache's hopes were to be realized twelve years later. On February 11, 1863, Gideon Welles, secretary of the navy, appointed Admiral Davis, Professor Henry and Professor Bache a "Permanent Commission" "to which shall be referred questions of science and art upon which the (navy) department may require information."⁴ En-

couraged by this governmental recognition, Bache, Peirce, Davis, Gould and Agassiz induced Senator Wilson, of Massachusetts, to introduce in congress a bill to incorporate the National Academy of Sciences. This passed the Senate and House on March 3, 1863, and was signed by the president on the same day.

The act of incorporation named fifty men of science as charter members, and limited the membership of the Academy to this number. A second act of congress, passed in 1870, removed this limitation. At present the amended constitution provides that ten new members may be elected annually, and fixes the limiting membership at one hundred and fifty. The actual number of names now on the roll is one hundred and thirty-two. In addition to these there are forty-nine foreign associates and one honorary member.

The list of incorporators contains many distinguished names: Agassiz, Alexander, Bache, Barnard, Dana, Davis, Gilliss, Gould, Wolcott Gibbs, Asa Gray, Guyot, James Hall, Henry Hilgard, Le Conte, Leidy, Lesley, Newberry, Newton, Peirce, Rogers, Rutherford, Silliman, Torrey, Whitney, Wyman—among others equally well known. Chosen from the country at large, and fairly representative of the science of the day, the membership was worthy of a truly national body.

The organization of the National Academy was "the first recognition by our government of the importance of abstract science as an essential element of mental and material progress."⁵ One of the objects in the minds of its founders was to confer distinction on men of science who had accomplished important original research, and thus to encourage and stimulate them

³ From the report for 1867 of Joseph Henry, president of the National Academy, *op. cit.*, p. 14.

³ *Op. cit.*, pp. 7, 8.

⁴ *Op. cit.*, p. 1.

to further effort. Another prime object was to aid the government in the solution of problems of a scientific nature. In 1863, the year of the Academy's incorporation, the civil war was in progress, and the government stood in need of just such advice as a body of able scientific men could supply. It will be seen later that the assistance of the Academy was often sought and rendered, not alone in this period, but also in subsequent years.

The idea that a democratic government could not consistently confer distinction upon its citizens, though held by some critics of the day, was not shared by Joseph Henry, whose words may again be quoted from the report cited above:

It is not enough for our government to offer encouragement to the direct promotion of the useful arts through the more or less fortunate efforts of inventors; it is absolutely necessary, if we would advance or even preserve our reputation for true intelligence, that encouragement and facilities should be afforded for devotion to original research in the various branches of human knowledge. In the other countries scientific discovery is stimulated by pensions, by titles of honor and by various social and official distinctions. The French academicians receive an annual salary and are decorated with the insignia of the Legion of Honor. Similar marks of distinction are conferred on the members of the Academy of Berlin and that of St. Petersburg. These modes of stimulation or encouragement may be considered inconsistent with our social ideas and perhaps with our forms of government. There are honors, nevertheless, which in an intelligent democracy have been and may be justly awarded to those who enlarge the field of human thought and human power. Heretofore, but two principal means of distinction have been recognized in this country, viz.: the acquisition of wealth and the possession of political power. The war seems to have offered a third, in bestowing position and renown for successful military achievement. The establishment of this Academy may be perhaps regarded as having opened a fourth avenue for the aspirations of a laudable ambition, which interferes neither with our national prejudices nor our political principles, and which only requires the fostering care of government to be-

come of essential benefit and importance not only to this, but all the civilized countries of the world.⁶

The special problems raised by the civil war emphasized the value of the services which the Academy might render the government, at a period when most of the scientific bureaus of later years were not yet organized. But the war had only an incidental bearing on the designation of the Academy as the scientific adviser of the nation. The desire of President Lincoln and his Secretary of State to receive advice from the Academy on more general questions is shown by the following letter from Secretary Seward to President Bache:⁷

DEPARTMENT OF STATE,
WASHINGTON, January 8, 1864.

Sir: I have the honor to acknowledge the receipt of your note of the 7th instant, tendering to this department the aid of the Academy of Sciences in any investigation that it may be thought proper to institute with a view to the great reform of producing an uniformity of weights and measures among commercial nations. Be pleased to express to the Academy my sincere thanks for this enlightened and patriotic proceeding, and assure them that, with the authority of the President, I shall be happy to avail myself of the assistance thus tendered to me, and to that end I shall at all times be happy to receive the suggestions of the Academy, or of any committee that may be named by it, in conformity with the spirit of the note you have addressed to me.

I am, Sir, your obedient servant,
WILLIAM H. SEWARD

We shall have occasion later to consider how the Academy has assisted the government in the solution of problems of the most diverse character.

The first meeting of the National Academy, attended by more than three fifths of the incorporators, was held at the University of the City of New York on April 22, 1863. Senator Wilson, who had introduced in the senate the bill of incorporation, ad-

⁶ *Op. cit.*, p. 14.

⁷ *Op. cit.*, p. 16.

dressed the Academy at the opening of the first session. After alluding to the fact that the idea of forming such an institution had long existed, he dwelt on the significance of unanimous action by congress at a time when the country was suffering under the burden of the great civil war. With its widely distributed membership, he felt that the Academy would contribute in the future toward the unity and indivisibility of the nation.

With Professor Henry in the chair, and other leaders of American science taking part in the deliberations, the work of the Academy was begun under the most favorable auspices. The constitution and by-laws were prepared by a strong committee, including such men as Agassiz, Benjamin Gould, Peirce and Silliman, with Bache as chairman. After three days of discussion they were adopted by the Academy, and finally ratified at the first Washington meeting, held in one of the committee rooms of the senate on January 4-6, 1864.

In the space at our disposal, we must content ourselves with a brief glance at the principal acts of the Academy during the fifty years of its existence, referring the reader to the work so often cited for further details. In accordance with the terms of the constitution, the members were divided into two classes, (*a*) mathematics and physics, and (*b*) natural history, each class having a chairman and secretary. The names of the sections, and the number of members in each, are given in the following table:

Class of Mathematics and Physics

	Number of Members
Sect. 1. Mathematics	6
Sect. 2. Physics	6
Sect. 3. Astronomy, Geography and Geodesy	9
Sect. 4. Mechanics	6
Sect. 5. Chemistry	3
	30

Class of Natural History

	Number of Members
Sect. 1. Mineralogy and Geology.....	6
Sect. 2. Zoology	5
Sect. 3. Botany	1
Sect. 4. Anatomy and Physiology	2
Sect. 5. Ethnology	0
Total	14
	44

It is interesting to contrast this organization with that existing at the present time:

Sect. 1. Mathematics and Astronomy....	23
Sect. 2. Physics and Engineering.....	25
Sect. 3. Chemistry	23
	71
Deduct names counted twice. 5	66
Sect. 4. Geology and Paleontology	24
Sect. 5. Botany	9
Sect. 6. Zoology and Animal Morphology. 18	
Sect. 7. Physiology and Pathology	15
Sect. 8. Anthropology and Psychology... 9,	
	75
Deduct names counted twice 9	66
Total	132

At the outset, two thirds of the members belonged to the class of mathematics and physics, and only one third to the class of natural history. At present, while the two classes no longer exist as such, it is easy to group the members in the same way. Deducting the names counted twice, we find that 66 would now fall in the first class, and exactly the same number in the second. Thus the discrepancy formerly existing between the two classes has been adjusted in the process of time.⁸

It is important to note that the division of members into sections is solely for the purpose of facilitating nominations for new elections, as now provided by the constitution.

⁸ DeCandolle notes a similar preference for the mathematical and physical sciences on the part of the Berlin Academy during the eighteenth century, which was subsequently adjusted by revision of the statutes. ("Histoire des Sciences et des Savants," 2 ed., p. 261.)

In view of the preponderance of physicists, it is not surprising that three fourths of the scientific papers read at the first Washington meeting were connected with the physical sciences. These papers were referred to the committee on publication, with instructions to publish, but the lack of funds for this purpose stood in the way. When the first volume of the *Memoirs* finally appeared in 1866, it contained but two of these papers. It was then planned to print the minor papers in the *Proceedings* of the academy, but this was never done. The first part of the first volume of the *Proceedings* was published in 1877. This contained the constitution and by-laws, reports on the principal business actions of the Academy, and much miscellaneous matter relating to resolutions passed, titles of papers presented, reports of committees, etc. Publication of the *Proceedings* was discontinued in 1895, after three parts had appeared.⁹ In 1881, 649 papers had been read at the scientific sessions. President Rogers, feeling that the Academy would have received much more recognition from the scientific world if these had been printed, strongly and repeatedly urged that the papers be collected annually and transmitted to congress with the report.¹⁰ Unfortunately this was never done, and the reports still give only an abstract of the proceedings, in which the papers appear by title. The importance of reviving and enlarging the *Proceedings* will be discussed in another article.

The Academy has published eleven volumes of *Memoirs*, containing 68 quarto papers, and seven volumes of *Biographical Memoirs* of deceased members, in addition to annual reports and reports of committees.

In view of the existence of a detailed

history of the Academy, it is quite unnecessary in the present paper to dwell at length upon the events of the first fifty years. A brief outline of the more important work of the Academy is nevertheless essential to clearness, especially in connection with the suggestions for the future which are to be presented later. We may, therefore, consider briefly: (1) the work of the members; (2) the Academy's work for the national government; (3) medals and trust funds, and (4) cooperation in research.

THE WORK OF THE MEMBERS

In his report for 1867 as president of the Academy, Joseph Henry spoke as follows of the conditions of membership:

It was implied in the organization of such a body that it should be exclusively composed of men distinguished for original research, and that to be chosen one of its members would be considered a high honor, and consequently a stimulus to scientific labor, and that no one would be elected into it who had not earned the distinction by actual discoveries enlarging the field of human knowledge.

... since the original organization, the principle before mentioned has been strictly observed, and no one has been admitted except after a full discussion of his claims and a satisfactory answer to the question, "What has he done to advance science in the line of research which he has especially prosecuted?"

And again, in his valedictory address to the Academy (1878), Henry returned to this subject.

For this purpose great care must be exercised in the selection of its members. It must not be forgotten for a moment that the basis of selection is actual scientific labor in the way of original research; that is, in making positive additions to the sum of human knowledge, connected with unimpeachable moral character.

It is not social position, popularity, extended authorship or success as an instructor in science, which entitles to membership, but actual new discoveries, nor are these sufficient if the reputation of the candidate is in the slightest degree tainted with injustice or want of truth.

⁹ *Op. cit.*, p. 44.

¹⁰ *Op. cit.*, p. 51.

These principles have been observed to the present day, sometimes in the face of great temptation to elect men eminent for achievements other than those of original research. Thus the Academy has counted among its members the large majority of the leaders of American science. While it is of course impossible to describe their individual contributions in these pages,¹¹ some remarks on the progress of American research since the foundation of the Academy will be given in a later paper.

THE WORK OF THE ACADEMY FOR THE NATION

In the first annual report of the president of the Academy, presented to congress in 1864, Professor Baché remarked:

The want of an institution by which the scientific strength of the country may be brought, from time to time, to the aid of the government in guiding action by the knowledge of scientific principles and experiments, has long been felt by the patriotic scientific men of the United States. No government of Europe has been willing to dispense with a body, under some name, capable of rendering such aid to the government, and in turn of illustrating the country by scientific discovery and by literary culture.

In a previous paper the distinctive position held by European academies as organizations of the government, and the services they render to the state, have been briefly described.¹² Here, as elsewhere in these papers, we must not overlook the special conditions which distinguish the National Academy from similar bodies abroad. The Royal Society and the Paris Academy of Sciences, dating from the earliest beginnings of science in England and France, have been the media through which the great advances of more than two

centuries have reached the world. Discovery after discovery, first presented at their meetings and published in their proceedings, has been rigidly associated in the public mind with these great societies, which have fostered science and encouraged the labors of investigators. Thus they have acquired a prestige and a power in the state which could arise in no other way. It is not enough for a nation to charter an organization and to authorize it to act as the adviser of the government in scientific affairs. Appreciation of the fundamental importance of science as the source of all industrial progress, and confidence in the body appointed to advise the nation, are obvious prerequisites to that cooperation between statesmen and men of science which is essential to complete success.

In spite of the disadvantage of a widely scattered membership, whose discoveries and contributions to science have always reached the world through other channels, and with no home of its own to focus attention on its activities, the National Academy has often been called into the service of the country. It will be sufficient to give here a list of the subjects on which the Academy has been consulted by the government, referring the reader to the "History of the National Academy" (pp. 201 to 331) for all details.

COMMITTEES APPOINTED BY THE ACADEMY ON BEHALF OF THE GOVERNMENT

1. Committees appointed in accordance with Acts of Congress.
 1871. On the Transit of Venus.
 1872. On Preparing Instructions for the *Polaris* Expedition.
 1878. On a Plan for Surveying and Mapping the Territories of the United States.
 1879. On a National Board of Health.
 1894. To Prescribe and Publish Specifications for the Practical Application of the Definitions of the Ampere and Volt.

¹¹ Biographies of the incorporators may be found in the "History of the National Academy," so often cited.

¹² SCIENCE, November 14, 1913.

1908. On the Methods and Expenses of Conducting Scientific Work Under the Government.
2. Committees appointed at the request of Joint Commissions and Committees of Congress.
 1884. On the Signal Service of the Army, the Geological Survey, the Coast and Geodetic Survey, and the Hydrographic Office of the Navy Department.
 1902. On the Establishment of a National Forest Reserve in the Southern Appalachians.
3. Committees appointed at the request of the President of the United States.
 1870. On the Protection of Coal Mines from Explosion by Means of Electricity.
 1902. On Scientific Explorations in the Philippines.
4. Committees appointed at the request of the Treasury Department.
 1863. On the National Currency (Confidential).
 1863. On Weights, Measures and Coinage.
 1863. On Saxton's Alcoholometer.
 1864. On Materials for the Manufacture of Cent Coins.
 1866. On the Prevention of Counterfeiting.
 1866. On Spirit Meters.
 1866. On Proving and Gauging Distilled Spirits and Preventing Fraud.
 1866. On Metric Standards for the States.
 1870. On the Effect of Chemicals on Internal Revenue Stamps.
 1873. On an International Bureau of Weights and Measures.
 1875. On Water-proofing the Fractional Currency.
 1875. On Means of distinguishing Calf's Hair from Woolen Goods (Confidential).
 1876. On Artificial Coloring of Sugars to Simulate a Lower Grade According to the Standard on which Duties are Levied (Confidential).
 1876. On the Use of Polarized Light to Determine the Values of Sugars.
 1877. On Demerara Sugars.
 1878. On Building Stone to be used for the Custom House at Chicago (no report).
 1882. On the Separation of Methyl Alcohol or Wood Spirits from Ethyl Alcohol.
 1882. On Glucose.
 1882. On Triangulation Connecting the Atlantic and Pacific Coasts (no report).
5. Committees appointed at the request of the Navy Department.
 1863. On Protecting the Bottoms of Iron Vessels.
 1863. On Magnetic Deviation in Iron Ships.
 1863. On Wind and Current Charts and Sailing Directions.
 1864. On the Explosion on the United States Steamer *Chenango*.
 1864. On Experiments on the Expansion of Steam.
 1877. On Proposed Changes in the American Ephemeris.
 1881. On the Transit of Venus.
 1885. On the Astronomical Day, the Solar Eclipse of 1886, and the Erection of a New Naval Observatory.
6. Committees appointed at the request of the War Department.
 1864. On the Question of Tests for the Purity of Whiskey.
 1866. On the Preservation of Paint on Army Knapsacks.
 1867. On Galvanic Action from Association of Zinc and Iron.
 1873. On the Exploration of the Yellowstone.
 1881. On Questions of Meteorological Science and its Application.
7. Committees appointed at the request of the Department of State.
 1866. On the Improvement of Greytown Harbor, Nicaragua.
 1903. On the Restoration of the Declaration of Independence.
8. Committees appointed at the request of the Department of Agriculture.
 1870. On Silk Culture in the United States.
 1881. On Sorghum Sugar.
9. Committees appointed at the request of the Department of the Interior.
 1880. On the Restoration of the Declaration of Independence.
1884. On Philosophical and Scientific Apparatus.
1885. On the Tariff Classification of Wools.
- 1886 and
1887. On the Morphine Content of Opium.
1887. On Quartz Plates used in Saccharimeters for Sugar Determinations.
1890. To Formulate a Plan for a Systematic Search for the North Magnetic Pole.

1896. On the Inauguration of a Rational Forest Policy for the Forested Lands of the United States.

It will be noticed that many of the questions referred to the Academy are of such a nature that, at the present day, they could be satisfactorily answered by one or another of the scientific departments of the government. This probably accounts for the fact that the requests for the Academy's assistance have become less numerous as the national laboratories and scientific bureaus have multiplied and improved. But after full allowance has been made for such wholly desirable developments, it remains true that questions of broad scope, requiring the cooperation of authorities in several fields of knowledge for their solution, must arise from time to time. In such cases the Academy can afford assistance obtainable in no other way, and an enlightened government will advantageously seek its counsel.

The overthrow of the spoils system in national politics will afford the Academy another opportunity to serve the nation. In France, when a professorship in the national university, or the directorship of a national observatory or laboratory falls

vacant, the Academy of Sciences is requested to present its first and second choice of a successor. The Minister of Public Instruction then appoints one of the nominees to the position. In the United States the need of such counsel is no less urgent than in France.

MEDALS AND TRUST FUNDS

Election to the National Academy has always been appreciated as a high honor by American men of science. Fortunately, however, the recognition and assistance the Academy has been able to afford to investigators has not been confined to the gift of this mark of distinction. From time to time trust funds have been established, the incomes of which are devoted to the award of medals or to grants for research. The will of Alexander Dallas Bache, first president of the Academy, directed that the residue of his estate, after the death of his wife, should be paid over to the National Academy of Sciences for the "prosecution of researches in Physical and Natural Science by assisting experimentalists and observers." Bache's excellent example has often been followed, with the results shown in the following table:

Fund	Established	Original Capital	Present Capital	Purpose
Alexander Agassiz.....	1910	\$50,000.00	\$50,000.00	General use of the academy.
A. D. Bache.....	1879	47,500.00	56,000.00	Researches in physical and natural science.
Cyrus B. Comstock.....	1907	10,000.00	10,337.50	Prize every five years for investigations in electricity or magnetism or radiant energy.
Henry Draper.....	1885	6,000.00	10,000.00	Medal for investigations in astronomical physics. (Surplus for research.)
Wolcott Gibbs.....	1893	2,673.17	3,000.00	Aid of chemical science.
Benjamin Apthorp Gould..	1897	20,000.00	20,000.00	Researches in astronomy.
O. C. Marsh.....	1912	9,377.65	9,377.65	Original research in the natural sciences.
John Murray.....	1911	6,000.00	6,000.00	To found Alexander Agassiz gold medal for original contributions in oceanography.
J. Lawrence Smith.....	1885	8,000.00	10,000.00	Lawrence Smith gold medal for original investigations of meteoric bodies. (Surplus for research.)
J. C. Watson.....	1883	18,666.82	25,000.00	Gold medal and money prize for astronomical investigations. (Surplus for research.)
Building Fund.....		7,000.00	7,000.00	

The importance of the part played by these funds in advancing science may be illustrated by reference to some of the results obtained.

The Agassiz Fund has proved to be of great value in meeting the general expenses of the Academy, for which there was formerly no provision except the dues of the members.

The Bache Fund made twelve appropriations to Hilgard for his magnetic survey of the United States, four to Langley for his important studies of the physical constitution of the sun, six to Wolcott Gibbs for his researches on complex inorganic acids and his studies of the action of chemical compounds upon the animal system, one each to Newcomb and Michelson for their classic determinations of the velocity of light, three others to Michelson for his equally fundamental optical researches, six to Rowland for his great work in mapping and identifying the lines of the solar spectrum, three to Pickering for his pioneer researches in stellar photography, two to Gould for his measurements of the Cordoba photographs of the southern heavens, six to Boss for his studies of solar and stellar motions and his precise measures of standard stars, and two to Osborn for the work of the Academy Committee on Correlation. These cases include only a fraction of the total number of grants from the fund.

The Barnard Gold Medal for Meritorious Services to Science, awarded every five years by Columbia University to the nominee of the National Academy, has been given to Rayleigh, Röntgen, Becquerel and Rutherford.

The first award of the Comstock Prize of fifteen hundred dollars was made last April to Professor Robert Millikan, of the University of Chicago, for his researches on the charge of the electron and related investigations.

The Henry Draper Gold Medal for astrophysical research has been awarded to Langley, Pickering, Rowland, Vogel, Keeler, Huggins, Hale, Campbell, Abbot and Deslandres. Several grants to assist investigation have also been made from the surplus income.

The capital of the Wolcott Gibbs Fund for chemical research is being increased by additions of accumulated income, and no grants are being made at present. The income of the Marsh Fund is also being added to the capital.

A large number of investigations have been assisted by the Gould Fund, including those of Doolittle, Parkhurst, Yendell, Newcomb, Leavenworth, Comstock and others. At present the income is used mainly for the support of the *Astronomical Journal*.

The Alexander Agassiz Gold Medal, established by Sir John Murray for oceanographic research, was awarded for the first time last April to Dr. Johan Hjort, of the Norwegian Fish Commission, for his valuable contributions to knowledge relating to deep-sea life.

The Lawrence Smith Gold Medal for the investigation of meteoric bodies has been awarded but once, to H. A. Newton, of Yale, for his researches on the orbits of meteors. Appropriations from the fund have supplied Yale University with apparatus for the photography of meteors, and provided for the publication of a catalogue of meteorites, for their chemical analysis and for the study of their luminous trains.

The Watson Fund has aided the important work of Chandler on the variation of latitude, and that of Comstock on the constant of aberration, in addition to many other important grants. Since 1901 the income has been very effectively used by Leuschner in the computation of the perturbations of the asteroids discovered by Watson. The Watson Gold Medal, with

one hundred dollars in gold, has been awarded to Gould, Schönfeld, Auwers, Chandler, Gill and Kapteyn for their astronomical investigations.

In view of its national charter, the high plane of its membership, and its special advantages as the representative of the United States in the International Association of Academies, the National Academy is most favorably qualified for the custody and efficient use of trust funds. Appreciation of this fact, amply indicated by the above list of gifts and bequests, should grow with the reputation of the Academy. It is safe to predict that the privilege of securing the Academy's aid in the control and disbursement of large sums for the benefit of science will be widely sought in the future. In this connection attention should be called to the present lack of medals and funds especially devoted to the recognition and aid of researches in mathematics, engineering, geology and various departments of biology and anthropology.

COOPERATION IN RESEARCH

As an agent for the furtherance of cooperative research, the National Academy occupies a unique position among American societies. In these days of far-reaching investigations, involving the common action of men of science distributed throughout the world, the great majority of cooperative projects are international in character. Here the peculiar advantage of the Academy appears. The International Association of Academies is made up of the national academies of sixteen countries. Each academy is pledged to support only such cooperative undertakings as are endorsed by the association. Thus the constituent members of this body, through their delegates at its triennial meetings, are most favorably placed for

the initiation and furtherance of such international movements.

As an illustration of the work already undertaken by the National Academy in this field, mention may be made of the International Union for Cooperation in Solar Research. In 1904, the Academy, through its Committee on Solar Research, invited various academies, physical and astronomical societies, and other organizations interested in the subject, to send delegates to a conference, with a view to the initiation of international cooperation in this field. Meetings have since been held at Oxford in 1905, Paris in 1907, Mount Wilson in 1910 and Bonn in 1913. The constituent societies, each of which is represented in the Union by a standing committee, are as follows:

The Royal Society of London, the Academies of Amsterdam, Barcelona, Berlin, Paris, St. Petersburg, Stockholm and Vienna, the Swiss Society of Natural Sciences, the Astronomical Societies of London, America, France and Canada, the Physical Societies of Berlin, Italy, Spain, France and America, the Society of Italian Spectroscopists, the Solar Physics Committee, the Solar Sub-committee of the International Meteorological Committee and the National Academy of Sciences.

The standards of wave-lengths which are being established by the Union, as the result of extensive cooperative studies, will be used universally by spectroscopists. International committees, appointed by the Solar Union, are studying the solar rotation, the spectra of sun-spots and the intensity of the solar radiation, on a common plan. Spectroheliographs are also in use, for the almost continuous photography of the sun, at the observatories of Kodai-kanal, India; Catania, Sicily; Potsdam, Germany; Meudon, France; Tortosa, Spain; Cambridge, England; Williams

Bay, Wisconsin; Tacubaya, Mexico; and Mount Wilson, California.

A new solar observatory, which is about to be established in New Zealand through the generosity of Mr. Thomas Cawthron, will fill the gap in longitude between California and India, and thus aid in keeping the rapidly changing phenomena of the solar atmosphere constantly under observation. At the Mount Wilson meeting of the Union, it was decided to enlarge its scope so as to include the whole range of astrophysics, and a representative committee was appointed to report on the classification of stellar spectra. It is now evident that the Solar Union is destined to play an increasingly important part in the field of international research.

The Solar Union is one of the organizations endorsed by the International Association of Academies, to which it makes regular reports. Another of the international investigations conducted under the auspices of the association is that of the Brain Commission, the American Committee of which is also closely related to the National Academy.

The Committee on International Paleontologic Correlation, appointed by the Academy in 1908, has recently completed its work. Aided by the Bache Fund, the committee has pushed forward the important work of correlating the geologic formations of Europe and America on the basis of their paleontologic contents. The results have been published in a series of papers, by members of the committee, most of which treat of the mammals of the tertiary epoch and the formations which contain them in North America. Marsh and Cope dealt with the formation of the American Eocene as units, even when their thickness ranged from 1,000 to 2,000 feet. These formational units have now been split up into sub-units, or life zones,

usually distinguished by geologic discontinuity. At the same time there has been a marked increase in the precision of recording the succession of species in certain formations which contain several levels of life zones, thus permitting exact comparisons with other life zones to be instituted. The importance of such work is obvious in connection with the trend and rate of development in different parts of the world, the possibility of geographic intercourse at certain epochs, and the cycles of physiographic and climatic change.

It is thus evident that the Academy is in a most favorable position to extend its operations in the field of international research, where the advantages of its national and representative character are felt to the full, and the disadvantages of its scattered membership are of minor importance.

From this brief survey it appears that the National Academy of Sciences, in spite of many obstacles, has played an important part in the development of American science. The time is now favorable for an extension of its work into new fields, which must be occupied if the special opportunities and obligations implied by the Academy's national charter are to be fully realized. In a later article some of the possibilities of future progress will be considered.

GEORGE ELLERY HALE

MOUNT WILSON SOLAR OBSERVATORY

*THE PLAN OF WORK IN CONNECTION
WITH A NEW MARINE LABORATORY
ON THE PACIFIC*

DURING the past summer a new marine station was erected at Laguna Beach, California. At this place the varied and rocky coast offers peculiar advantages for the study of plant and animal life. The situation, too, is convenient for those in southern California, being within fifty miles from Los Angeles and easily accessible from other cities and towns.

The wealth of life at Laguna has attracted students of Pomona College during the past three years to visit this region for summer work. The growing interest of students and others in sea-side studies led to the erection of an adequate building. This contains two general laboratories, dark room, store rooms, aquarium for living specimens and nine private laboratories with fresh and salt water. There is in addition to the main building a tank house with two more rooms. The laboratory is established chiefly for teaching purposes, but there are facilities for a limited number of investigators. The plan of investigation and to some extent the work of teaching is organized along a definite line.

The laboratory is but one station for zoological work. The other center is situated fifty-five miles inland at Pomona College, Claremont. Between the two stations there are ranges of hills, low mountains with small streams and lakes, and great level stretches. Back from Claremont and the college buildings the mountains of the San Gabriel range, often covered with snow, rise to an elevation of ten thousand feet, and beyond them stretches the desert with its lower ranges and arid valleys. In this area a careful survey is to be made of all groups of living things, not all at once, but bit by bit, not by a few, but by many.

Some of the advantages of the location and of the climate are such as to contribute to the success of the enterprise. Field work may be undertaken at all times during the year at Laguna and to a large extent about Claremont. One of the chief recreations of the students is in the form of long or short expeditions into the mountains, and their services are enlisted to obtain specimens from different regions of high and lower altitude. In this way many interesting things have already been brought to light. Some species, for instance, are found to have a very local distribution on some mountain slope or in the depths of some scarcely accessible canyon. Besides the collection of specimens, there are possibilities in the way of observation of large animals, such

as mountain sheep, deer, mountain lions and many smaller mammals and birds.

One of the features of class exercises in introductory courses is the collection of entomological and other zoological specimens with full data, as well as field work of other kinds. By these means the student obtains knowledge of the different animal groups, and the rough materials for more careful investigations are collected. For the more advanced workers special groups or special problems are studied in the field or in the laboratory. The necessary determinations are made so far as possible by the students, but their material is sent to specialists for confirmation. The results of this survey are not to be confined to mere records of species, but so far as possible in every group an attempt will be made to determine the adaptations to the environment, the relation of the insects and other forms to the cultivated plants in the region. Records are to be kept of climatic conditions from season to season and from year to year. Specimens collected at various times are kept with date and locality label until special students or specialists can determine them. At no time will the work on a particular family, order or class be regarded as finished, but from month to month new records are to be added. Although systematic investigations may come first in point of time, the effort will be made to determine other things from the material as occasion arises. This will necessitate a broad study of plant forms, topographical and climatic factors, as well as the interrelations of the animals studied. Knowledge of life histories and habits will also be a natural feature of the work.

There is so much ground to cover in this great outline, that it will be years before much of an impression is made upon the unknown, and it may be a long time before certain isolated facts seem to have any value or bearing on the rest. It is the purpose before long to have a special fireproof room to keep the specimens and records for the use of present workers and for the future. These data ought to be very valuable in a few years to many special

investigators. Some of the results of the work appear from time to time in the *Journal of Entomology and Zoology*, which is published quarterly by the college.

There are of course great gaps in the whole plan. Only here and there can a little be done at a time, but it is believed that by encouraging classes and individuals to collect data and specimens, and, when well trained, to record observations of a more difficult nature, we have an opportunity to do a great work which is unique and can not help but benefit all who partake in the effort. Whatever may be the value of the facts obtained and tested, whatever the value of the discovery of new species or new adaptations, there is, I believe, the value of method for the beginning student or the more advanced one. It will not matter what study he pursues after leaving college for the university; an awakened interest in things out of doors, an increased accuracy of observation should result. It seems to me too that the thought of contributing something to science, no matter how small a fact, ought also to be a stimulus in the future as it has been in the past.

WILLIAM A. HILTON

POMONA COLLEGE,
CLAREMONT, CAL.

WINSLOW UPTON

WINSLOW UPTON, professor of astronomy and director of the Ladd observatory at Brown University, died of pneumonia, at Providence, on January 8, in the sixty-first year of his age. His forbears were of north England origin but early in the seventeenth century the founder of the New England family emigrated to Massachusetts. Professor Upton was born on October 12, 1853, and was the fourth son of James Upton, a prominent merchant of Salem, Mass., and a liberal contributor to Brown University. Entering Brown in 1871 he was graduated as valedictorian of the class of 1875. He had attained to almost equal excellence in the pursuit of studies in ancient classics and in science, but he felt that his forte was rather in the line of scientific investigation. So he turned to the University of Cincinnati for

graduate work in astronomy and was there awarded the degree of A.M. in 1877. His alma mater conferred on him the honorary degree of Sc.D. in 1906.

He was assistant in the astronomical observatory at Harvard, 1877-79; assistant engineer in the U. S. Lake Survey at Detroit, 1879-80; computer in the U. S. naval observatory at Washington, 1880-81; computer and assistant professor in the U. S. Signal office, 1881-84.

In 1884 he was appointed professor of astronomy at Brown University and since 1891 he has been both professor of astronomy and director of the Ladd observatory (the gift of the late Governor H. W. Ladd) which was built under his supervision. The facilities of the observatory have been used chiefly to aid in the instruction of the university, in the maintenance of a local time service, and in regular meteorological observations in cooperation with the U. S. Weather Bureau.

Professor Upton has been connected with a number of important scientific parties. He was a member of the U. S. astronomical expeditions to observe the total eclipse at Denver, Colorado, in 1878, and at the Caroline Islands in the South Pacific, in 1883. He also observed the solar eclipse of 1887 in Russia, that of 1889 in California, of 1900 in North Carolina, and during a sabbatical year, 1896-97, he was attached to the southern station of the observatory of Harvard College, at Arequipa, Peru.

Professor Upton's publications, for the most part in the department of meteorology, include the following:

1. "The Solar Eclipse of 1878," a lecture before the Essex Institute (*Bulletin of the Essex Institute*, Vol. 11. 1879; reprinted, pp. 19).
2. "Photometric Observations Made Principally with the Equatorial Telescope of Fifteen Inches Aperture During the Years 1877-79"; by E. C. Pickering, C. Searle and W. Upton (*Harvard Astr. Obs. Ann.*, Vol. 11, 1879, pp. 317).
3. "Information Relative to the Construction and Maintenance of Time-balls" (Wash-

ington, 1881, pp. 31 + 3 pls., U. S. War Dept. Professional papers of the Signal office, No. 5).

4. "Lectures on Practical Astronomy," 1882 (Report of the Chief Signal Officer, Washington, 1882, pp. 104-120).

5. "On the Methods Adopted in the Computation of Barometric Reduction Constants" (Report of the Chief Signal Officer, Washington, 1882, appendix 61, pp. 826-846, Washington, 1883).

6. "The Use of the Spectroscope in Meteorological Observations" (U. S. signal service notes, No. IV., pp. 7 + 3 pls., Washington, 1883).

7. "Report of Observations Made on the Expedition to Caroline Islands to Observe the Total Eclipse of May 6, 1883" (reprinted from *Memoirs of the National Academy of Sciences*, Vol. 2, Washington, 1884, pp. 64 + 7 pls.).

8. "Distribution of Rainfall in New England February 10-14, 1886, from Observations reported to the New England Meteorological Society" (reprinted from *SCIENCE* of March 19, 1886, *Providence*, 1886, pp. 8).

9. "An Investigation of Cyclonic Phenomena in New England" (1887).

10. "Meteorological Observations During the Solar Eclipse August 19, 1887, at Chlmostina, Russia" (reprinted from the *American Meteorological Journal*, Ann Arbor, 1888, pp. 25).

11. "The Storm of March 11-14, 1888" (reprinted from *American Meteorological Journal*, May, 1888, pp. 19).

12. "Characteristics of New England Climate" (*Harvard Astr. Obs. Ann.*, Vol. 21, 1890, pp. 265-273).

13. "Meteorological and Other Observations Made in Connection with the Total Solar Eclipse of January 1, 1889, at Willows, California," by W. Upton and A. L. Rotch (*Harvard Astr. Obs. Ann.*, Vol. 29, 1892, pp. 34 + 2 pls.).

14. "Star Atlas, Containing Stars Visible to the Naked Eye and Clusters, Nebulae, and Double Stars Visible in Small Telescopes . . . and an Explanatory Text" (Boston, Ginn and Co., 1896, pp. iv + 34).

15. "Geographical Position of Arequipa Station" (*Harvard Astr. Obs. Ann.*, Vol. 48, 1903, pp. 52 + 1 pl.).

He was also the contributor of numerous short articles to the *Astronomische Nachrichten* since 1877, to *Zeitschrift für Meteorologie*, *Siderial Messenger*, *Popular Astronomy*, *Science*, *American Meteorological Journal*, *Astronomical Journal* and other scientific publications. For over twenty years he wrote monthly letters on astronomical topics for the *Providence Journal* and was editor of the astronomical part of the *Providence Journal Almanac* 1894-1910.

Professor Upton was a fellow of the American Association for the Advancement of Science, a member of the Deutsche Meteorologische Gesellschaft, of the Phi Beta Kappa, Sigma Xi Societies and of the Delta Upsilon fraternity. He married, in 1882, Miss Cornelia Augusta Babcock, of Lebanon Springs, N. Y., and their two daughters are graduates of Smith College.

At Brown University Professor Upton was secretary of the faculty 1884-91, Dean 1900-1901, one of the committee on organization of the movement to increase the university endowment 1910-11; and, for more than a score years, a member of important administrative committees. He was also an active church worker, endowed with rare simplicity, genuineness, and warmth of Christian faith, and, at different times, glee-club and choir leader, and organist. His musical talents (so often the possession of astronomers and mathematicians) were inherited from his father; the George P. Upton who has given us many a pleasing volume on musical topics is a distant relative.

Professor Upton was possessed of unusual scientific ability, coupled with brilliancy and rare clarity of thought and power of exposition of intricate subjects. Too much, it seemed to some, did the university demand of his time and strength to deal with administrative problems, when he might so easily have multiplied his contributions to science. That extensive projects in this direction were contemplated are indicated by manuscripts left behind. He had a good deal of personal

magnetism, a joyous appreciation of refined humor, and was constantly in demand as a lecturer. In the class-room he displayed exceptional power to arouse enthusiasm. He was tactful and of judicial temper, a man inspired with the highest ideals in the conduct of life and possessed of unflinching patience, of great tenderness of heart and kindness of spirit. He was beloved alike by colleagues and students.

Only a week ago, our friend was in the class-room. Because of the tragic swiftness of his passing—for just the other day he seemed to us but in the prime of bodily and mental vigor—a pregnant hush of introspection pervades the academic community. This afternoon his body was borne to his native city.

“Warte nur, balde
Ruhest du auch.”

R. C. ARCHIBALD

BROWN UNIVERSITY,
January 10, 1914

SCIENTIFIC NOTES AND NEWS

The fourth annual award of the Willard Gibbs Medal, founded by Mr. William A. Converse, will be made by the Chicago Section of the American Chemical Society to Dr. Ira Remsen, of Johns Hopkins University. The previous recipients of this medal are Professor Svante Arrhenius, Professor Theodore W. Richards and Dr. Leo H. Baekeland. The formal presentation will be made to Dr. Remsen at the May meeting of the Chicago Section of the American Chemical Society. Dr. Remsen has formally signified his acceptance of this award. The jury of award which selected Dr. Remsen comprised Mr. William Brady, Mr. G. Thurnauer, Dr. E. C. Franklin, Dr. W. R. Whitney, Professor J. H. Long, Professor J. Stieglitz, Professor Alexander Smith, Professor W. A. Noyes, Mr. E. B. Bragg, Mr. S. T. Mather, Professor W. H. Walker and Professor T. W. Richards.

At the recent meeting of the American Physical Society at Atlanta, in connection with the American Association for the Advancement of Science, the following officers were elected for 1914: *President*, Ernest Mer-

ritt, of Cornell University; *Vice-president*, Karl E. Guthe, of the University of Michigan; *Secretary*, A. D. Cole, of the Ohio State University; *Treasurer*, J. S. Ames, of the Johns Hopkins University; *Members of Council*, G. K. Burgess, of the Bureau of Standards, and D. C. Miller, of the Case School of Science; *Managing Editor of Physical Review*, F. Bedell, of Cornell; *Editorial Board*, A. G. Webster, of Clark University, C. E. Mendenhall, of the University of Wisconsin, and H. A. Bumstead, of Yale University. The next two meetings of the Physical Society will be at Columbia University, New York, on February 28, and at the Bureau of Standards, Washington, on April 24 and 25.

DR. AUGUST WEISMANN, professor of zoology at Freiburg, celebrated on January 17 his eightieth birthday.

THE Imperial Society of the Friends of Natural History, Anthropology and Ethnology, of Moscow, have elected Professor W. M. Davis to permanent membership.

THE Imperial Academy of Sciences of St. Petersburg has elected Sir Edward Thorpe as a corresponding member.

PROFESSOR SILVANUS P. THOMPSON has been elected a corresponding member of the Academy of Sciences of Bologna.

PROFESSOR JOHANNES ORTH, head of the pathological laboratory at the University of Berlin, has been elected an honorary member of the London Institute of Hygiene.

DR. JOSEPH T. ROTHROCK, who is now seventy-four years old, has resigned as a member of the Pennsylvania State Forestry Board after serving for twenty years, in order to devote more time to private work.

OCTAVE CHANUTE medals have been awarded by the Western Society of Engineers for the best three papers presented during the year 1913 as follows: mechanical and electrical engineering, Mr. W. L. Abbott on “The Northwest Station of the Commonwealth Edison Company”; general engineering, Mr. Onward Bates on “Arbitration”; civil engineering, Mr. D. W. Mead on “The Cause of

Floods and the Factors that Influence Their Intensity."

MONTYON prizes, each of the value of \$500, have been given by the Paris Academy of Sciences to Mme. Lina Negri Luzzani, for her studies on the corpuscles discovered in the nervous system of rabid animals, to L. Amhard, for his memoir on renal secretion, and to MM. A. Raillet, G. Moussu and A. Henry, for their researches on distomatosis in ruminants. Awards of \$300 each have been made to M. Marquis, for his memoir on mercuric chloride in surgery, to M. Legrange, for his work on the treatment of chronic glaucoma, and to Fernand Bezançon and S. L. de Jong, for their treatise on the examination of sputa.

PROFESSOR W. E. CASTLE, of Harvard University, has been reappointed a research associate of the Carnegie Institution for a period of five years with an annual grant of \$2,500 in support of his researches in heredity. This is the third five-year appointment as research associate received by Professor Castle from the Carnegie Institution.

THE American Microscopical Society held only business meetings at Atlanta. Professor Charles Brookover, Little Rock, Arkansas, of the University of Arkansas Medical School, was elected president; Miss Margaret Ferguson, Wellesley College, first vice-president, and Dr. H. L. Shantz, Bureau of Plant Industry, Washington, D. C., second vice-president. T. W. Galloway, of Millikin University, was reelected secretary and editor of the *Transactions*. Mr. Magnus Pflaum, of Meadville, Pa., who has served the society so faithfully for years as its custodian and has built up the research fund to nearly \$5,000 was elected to honorary membership.

PROFESSOR CARLOS E. PORTER, director of the *Revista Chilena de Historia Natural* and professor of zoology and entomology at the Agricultural Institut of Chile, has been made vice-president, for 1914, of the Sociedad Científica de Chile and honorary professor of zoology at the Agricultural College of the University of Manaus (Brazil).

DR. T. A. JAGGAR, director of the observation station at Kilauea, Hawaii, has gone to Japan, to study the phenomena of the volcanic eruption on Sakura.

DR. J. B. JOHNSTON, professor of anatomy in the University of Minnesota, has sailed for Europe, on leave of absence for the second semester. He will return about September 1.

DR. OTIS WILLIAM CALDWELL, associate professor of botany in the School of Education and dean of University College at the University of Chicago, has been granted leave of absence during the next two months for a visit of inspection to the high schools and colleges of the south with reference to the teaching of science.

LLOYD W. STEPHENSON, of the United States Geological Survey, is to be at the University of California from January to June, 1914, as acting professor of paleontology, during the half year's absence of Professor J. C. Merriam, who is spending this semester preparing for the publication of some of the results of his collections from the pleistocene asphalt beds of Rancho LaBrea, near Los Angeles.

MRS. HUNTINGTON WILSON has established for the year 1914 a lectureship in eugenics, and has placed a fund of \$2,500 for the purpose in the care of the Eugenics Record Office of Cold Spring Harbor, N. Y. Mr. A. E. Hamilton, of Clark University, has been appointed to this lectureship and will be available for colleges, societies and clubs.

PROFESSOR GEORGE C. WHIPPLE, of Harvard University, delivered a lecture on "Relative Values in Sanitation" before the Science Club of the University of Wisconsin on January 22, 1914.

PROFESSOR ARTHUR H. BLANCHARD, in charge of the graduate course in highway engineering at Columbia University, on January 26 delivered illustrated lectures at the University of Illinois on the subjects: "Bituminous Surfaces and Bituminous Pavements" and "Modern Developments in Highway Engineering in Europe."

PROFESSOR GEO. GRANT MACCURDY, of Yale, delivered the fourth of the winter series of

public lectures under the auspices of the Pennsylvania State Museum and the Harrisburg Natural History Society at Harrisburg, Pa., on January 21, 1914. He lectured upon "The Antiquity of Man in the Light of Recent Discoveries."

DR. MAYVILLE W. TWITCHELL, the assistant state geologist of New Jersey, has just finished a course of five lectures on "The Geology of New Jersey" before the combined classes of the department of geology at Rutgers College.

PROFESSOR BALDWIN SPENCER lectured on January 27 before the Royal Anthropological Institute on the life of the Australian tribesmen. The lecture was illustrated by means of kinematograph films and phonograph records.

MR. ALEXANDER GEORGE McADIE has been given the title Abbott Lawrence Rotch professor of meteorology, in memory of the late Professor Rotch.

A COMMITTEE has been formed to establish scholarships in memory of Lord Avebury at the University of London. The sum of \$15,000 has already been subscribed for this purpose.

THE centenary of the birth of Claude Bernard was celebrated at the Collège de France on December 30.

THE tablet unveiled at King's College by Lord Rayleigh on January 14 to the memory of Lord Lister bears the following inscription:

In affectionate and respectful memory of Joseph Baron Lister, F.R.S., O.M., professor of clinical surgery in King's College from 1877-1892, and for many years consulting surgeon to the King's College Hospital, member of the council and life governor of the college, this tablet is erected. His name will be handed down to posterity as the founder of antiseptic surgery, one of the greatest discoveries in history, and a source of inestimable benefit to mankind.

MR. W. D. MARKS, professor of mechanical engineering at the University of Pennsylvania from 1876 to 1887, later a consulting engineer in New York City, has died at the age of sixty-four years.

PROFESSOR AARON HODGMAN COLE, of the Chicago Normal School, known for his writings and lectures on biology, has died at the age of fifty-seven years.

THE death is announced of Dr. J. Schreiner, astronomer in the Potsdam Astrophysical Observatory.

THE late Edward Ginn has bequeathed \$800,000 for the World's Peace Foundation which he had established; Tufts College receives \$10,000 and one tenth the residue of his estate.

THE Swedish Antarctic committee, an association formed last year with Admiral Palander at its head, has planned an expedition which will start in the autumn of 1915. The cost of the expedition will be \$72,360.

DISPATCHES from Dr. Percival Lowell at his observatory at Flagstaff, Ariz., announce that he is using the forty-inch Clark reflecting telescope on Mars with full aperture. The definition he declares to be perfect, the canals being sharp lines.

AN organization dinner for the discussion of plans for the International Electrical Congress at San Francisco in September, 1915, is to be held at the Engineers' Club, New York City, Wednesday evening, February 25.

ARRANGEMENTS are being made for an exhibition of physical apparatus at the joint meeting of the American Physical Society and of the electrophysics committee of the American Institute of Electrical Engineers, to be held on April 24 and 25 at the Bureau of Standards, Washington. The opening of the new electrical building of the bureau will add interest to the occasion, and incidentally will furnish abundant room for a large exhibit of apparatus. It is hoped that designers and makers of apparatus will unite to make this a truly representative exhibition. Unfortunately expenses of transportation and mounting of exhibits must be borne by the exhibitors. The Bureau of Standards can give only a limited amount of help in mounting. Exhibits of any considerable size should be unpacked and mounted, and repacked and cared

for by the exhibitors. Any packages or boxes sent to the Bureau of Standards should be clearly marked "for Physical Society exhibit" and *prepaid*.

FORESTERS and lumbermen see in a decision of the Treasury Department in regard to the administration of the income tax a strong argument for forestry. As they interpret the opinion of the treasury officials they understand that no timberlands shall be subject to the tax until the lumber is cut and marketed and that then the profit only will be subject to an income tax assessment. In other words, all costs will be deducted before the tax is levied, and these will cover the cost of growing the timber, including the cost of planting where necessary and of protecting the growing crop from fire and other depredation. This decision was based upon a request for information made by P. S. Ridsdale, secretary of the American Forestry Association. He asked if there would be a tax on the value of the yearly growth of timber whether it was cut or not, and also whether an income tax would be assessed on the values of the timberland. In reply, the Treasury Department said that the gain from the cutting and disposal of stumpage is realized in the year during which the timber is cut and disposed of, and that the amount received in excess of the cost of such timber is profit, and should be so accounted for as income for that year.

UNIVERSITY AND EDUCATIONAL NEWS

THE late Morrill Wyman, of Cambridge, has left to Harvard College \$50,000, to be used to promote good citizenship by the study of republican government. Further, one half of the residue of his estate, which is said to be large, is left to Harvard to establish a fund in memory of his father, to be known as the Morrill Wyman Medical Research Fund, to provide for the study of "the origin, results, prevention and treatment of disease." A further sum of \$50,000 will ultimately go to this fund. Another fourth of the residue of the estate is left to the Massachusetts Institute of Technology, to be used in aid of deserving and promising students.

THE gift of \$125,000 by an unknown friend for a children's department has now completed the fund of \$615,750 which has been raised for building a new teaching hospital for the University of California Medical Department. Among the other principal contributors are John M. Keith, of San Francisco, who has given \$150,000 in memory of his wife, and four members of the Crocker family, who have given \$150,000 in memory of George Crocker, himself the founder of the Crocker cancer research fund of Columbia University. The givers of the George Crocker fund are Mrs. Harriet F. Alexander, \$50,000; William H. Crocker, \$50,000; Charles Templeton Crocker, \$25,000, and Mrs. Malcolm Whitman, \$25,000.

THE University of Chicago will erect three new buildings this year at a cost of \$800,000. They are the women's gymnasium and club, the geology building and the classics building. Announcement has been made that building operations will be started so that cornerstones of the geology and classics buildings may be laid at the March convocation.

WITH the object of stimulating interest in scholarship among high school students of the community, four competitive scholarships have been established in Adelbert College of Western Reserve University.

THE sixth session of the graduate school of agriculture will be held at the College of Agriculture of the University of Missouri, beginning on June 29, 1914, and continuing four weeks. Only persons who have completed a college course and taken a bachelor's degree will be admitted to the privileges of the school, except that admission may be granted to non-graduates who are recommended by the faculties of the college with which they are associated as persons properly qualified to profit by advanced instruction in agriculture. The faculty will include leading scientific men and experts from the U. S. Department of Agriculture, the agricultural colleges and experiment stations, and other universities, colleges and scientific institutions in America and Europe.

MERRITT BERRY PRATT, now deputy supervisor of the Tahoe National Forest, has been

appointed assistant professor of forestry in the University of California, in the new department of which Walter Mulford, now professor of forestry at Cornell, is next August, to become the head.

DR. ALBERT N. GILBERTSON has charge of the instruction in anthropology at the University of Minnesota in the absence on leave of Dr. A. E. Jenks.

DR. OSCAR PERRON, of Tübingen, has been called to a professorship of mathematics at Heidelberg.

DISCUSSION AND CORRESPONDENCE

WHAT WAS THE CAUSE OF THE ESKERS?

TO THE EDITOR OF SCIENCE: Eskers are features of the earth's surface well known to all students of glacial phenomena. They are more or less well defined ridges composed of mixtures of sand, gravel, clay and boulders, having a direction generally parallel to that of the movement of the latest ice sheet that covered the region where they occur, or normal to the front boundary of the sheet, and they often have a length of many miles, though entire continuity rarely exists throughout the length of any one such ridge or series of ridges having such relations as to be considered as one esker. In some cases such ridges have a striking uniformity in height and cross section, with an abruptness of side slopes and an alignment that suggest an artificial embankment like that for a railroad or a levee. Other forms that have been called eskers are flattened and spread out, broken into detached ridges that often depart from parallelism, and these are frequently associated with knolls and irregular hummocks and valleys that would not be considered as related in any way to esker forms if they stood by themselves. Eskers in the United States have been described and illustrated in several publications of the United States Geological Survey, as well as in various papers and geological text-books. They are numerous and extensive in the eastern part of that portion of North America that was covered by the latest ice sheet, particularly in Maine, New Brunswick and the

eastern Canadian provinces. Several examples on a smaller scale are found in the Great Lakes region of the United States. The writer has examined more especially the eskers near Circleville, south of Norwalk, and near Kenton, in Ohio; the one north of Muncie, Indiana, the fine example near Kaneville, Ill., and the strikingly uniform and conspicuous esker ridge at Mason in southern Michigan. Casual examination has also been made of similar ridges in Ontario, Canada.

The theory to account for these ridges which is most often met with is that they were formed by stream action, in crevices or in tunnels under the ice, during the period of recession or withdrawal of the ice sheet. From the published descriptions and views and sketches of eskers and from the examinations above referred to, I became satisfied that this theory was untenable, although there are some evidences that stream action has had a secondary and modifying effect on the final esker forms in some cases. I concluded that the eskers resulted primarily and principally from cracks in an ice sheet of moderate thickness covering approximately smooth and level areas of considerable extent; these cracks becoming the locus of the accumulation of the esker material from the lateral "shove" of the separated parts of the ice sheet under the influence of seasonal changes of temperature. This action resulted in the upheaval and breaking of the ice along the initial crack, and the melting of the resulting broken ice at a rate greater than that of the main ice sheet due to increase of exposed surfaces, with the accumulation of the general surface earthy material as well as that imprisoned within the ice itself along a more or less well-defined line. This earthy material remained, of course, after the ice disappeared, and it was often modified to a greater or less extent by flowing water during the melting of the ice. I prepared a tentative memorandum setting forth this view some three years or more ago, but it was not published. The illustrated supplement of the *New York Times* of November 23 contains a photographic view of a "pressure ridge" in a sheet

of sea ice, taken from Captain Scott's narrative of his South Pole expedition, which recalls the subject to mind. This picture seems to afford a very decided support for the above theory.

I conceive that the conditions under which eskers were formed were similar to those illustrated by this view of a pressure ridge, although in this case the ridge is understood to have been formed in ice resting on water. It is possible that at the time of the formation of the esker ridges the movement of the ice was facilitated by water underlying the sheet over considerable areas, so that the ice was partially afloat at least for portions of each year.

Very pronounced ridges of boulders and other material are formed under weather conditions now existing around the shores of small interior lakes in cold climates by the "push" of the ice that covers the lakes each winter.

I believe that the seasonal variations in temperature that must have occurred even during the low average temperature of the glacial period, with resulting changes in the internal structure and movements of the ice, constituted an influence of more importance in connection with general glacial phenomena than has heretofore been recognized.

The "trough" or depression along one or both sides of the ridge which sometimes occurs as a marked feature in connection with an esker was probably due primarily to the greater scooping and shoving effects of the ice on the underlying earth material immediately adjacent to the ridge, on account of the broken condition of the ice and the increased weight resulting from increased thickness and the superimposed broken blocks and fragments. The esker ridge itself and such side depressions would sometimes determine or materially modify the immediate post-glacial drainage of the locality, when the depressions would become still further emphasized by stream erosion during and after the melting of the ice. Furthermore, the "delta formation" sometimes found near the end of the esker is thus explained.

A theory similar to the above is applicable to certain irregular detached groups of knolls

or hummocks and short ridges with intervening troughs and hollows, called *kame* areas. Some examples of these may mark a sort of focus for the lateral shove from various directions of the surrounding ice sheet. In at least one locality that has been studied in considerable detail the assumption of the formation of an interglacial ridge by a process similar to that described above, but with a direction transverse to that of the general movement of the ice sheet, seems to afford a clue to an explanation of several surface features of the vicinity, and possibly this may also apply to some special cases where there has been difficulty in fitting the terminal moraine theory with entire satisfaction.

The probability of an extensive ice sheet of moderate thickness in comparison with that of earlier ice "invasions" of the same area, and as the final stage of the glacial period for the region in question, suggests other interesting deductions in connection with the causes of present surface forms.

JOHN MILLIS

November 25, 1913

MATTER AND MEMORY

ON reading with interest the article of Professor R. D. Carmichael, *SCIENCE*, December 19, I find on page 869 a statement which can not pass as entirely general: "... mind ... has chosen to assume that matter is without memory."

While in abstract reasoning we prefer to assume that matter has no memory, nevertheless we well know that in all too many cases this assumption is made for simplicity, not for exactness. The existence of zero drift, permanent set, elastic, magnetic and dielectric hysteresis, etc., so complicates the actual conditions, by making them dependent on the previous experiences of the material under consideration, that we can not set up ideally exact general equations. The complications are by no means as overwhelming as those, for example, which present themselves in dealing with warm-blooded animals, but they are real. What the instrument-maker desires is matter which does forget, whether he be interested in galvanometer suspensions or transformer cores. To speak figuratively, the suspension "re-

members" previous torsion, and precision is impaired; the iron "remembers" the preceding cycle, and energy is wasted in concentrating its wandering attention.

Not the least remarkable thing about falling stones, and gravitational action in general, is the lack of hysteresis, or memory.

NEW HAMPSHIRE COLLEGE,
DURHAM, N. H.

LAG AND LEAD WITH A BRAUN TUBE

IN arranging an experiment to show lag and lead with a Braun tube I hit upon a method that was very effective and may possibly be of use to others.

The tube, with its axis horizontal, was excited by an induction coil with a break of variable speed. Two coils were used to produce the magnetic field, one with its axis vertical, and the other with its axis horizontal, and both with axes perpendicular to the axis of the tube. The distance of the one coil from the tube could be varied. If an alternating current was sent through the coil with horizontal axis it would produce a vertical line on the fluorescent screen when the tube was excited. If now the period of the vibrator of the coil was changed until the frequency of the alternating current was nearly equal to a multiple of the frequency of the coil the stroboscopic effect would make the spot of light move slowly up and down on the screen. With the current flowing through the other coil the spot would move back and forth on the screen. When the alternating current from the same source is led into both coils the spot moves up and down diagonally at an angle of 45°.

If now considerable inductance is introduced into one circuit the spot will move around in an ellipse in one direction, but if a condenser takes the place of the inductance the spot moves in an ellipse in the *opposite* direction. Varying the inductance varies the width of the ellipse so that the amount of lag or lead is roughly indicated. If both inductance and capacity are put into the same circuit the width of the ellipse is reduced,

showing the neutralizing effect of capacity on inductance.

A SECOND OCCURRENCE OF ICHTHYOSAURIAN REMAINS IN THE BENTON CRETACEOUS

IN 1905¹ Dr. John C. Merriam announced the discovery of Ichthyosaur-like remains in the Benton of Wyoming. That it was not an accidental occurrence now appears to be indicated by the finding of a second specimen in these same beds. Recently I have received for examination a single badly worn vertebral centrum, collected during the summer of 1913 by Mr. C. J. Hares, of the U. S. Geological Survey in the Mowrey shales, some 12 miles west of Casper, Wyoming. This vertebra is of the typical biconcave ichthyosaurian type and in its present condition is indistinguishable from those of *Baptanodon*. The fragmentary nature of the specimen precludes the possibility of determining its true generic affinities, but as recording a second occurrence of ichthyosaur-like remains in the Benton, the specimen is at the least of interest.

CHARLES W. GILMORE

U. S. NATIONAL MUSEUM

A MISNAMED PORTRAIT OF JOHN SHAW BILLINGS

TO THE EDITOR OF SCIENCE: Dr. S. Weir Mitchell's appreciative memoir of the late Dr. Billings in your current issue is not accompanied by a picture and does not refer to one; so the present note may be acceptable. On p. 223 of Vol. VII. of the "Photographic History of the Civil War" the upper right portrait represents Dr. Billings during the war as an assistant surgeon with the rank of first lieutenant; it is misnamed "Brevet Lieut. Col. J. J. Woodward." This legend really belongs to the lower left portrait, which in turn is misnamed "Brevet Major C. B. Greenleaf." To which of the two other portraits this belongs I can not say. In this connection may be noted another error in the work above named. In Vol. X., on p. 263, the portrait named "David R. Jones" is that of Samuel

SCIENTIFIC BOOKS

Researches in Magneto-Optics, With Special Reference to the Magnetic Resolution of Spectrum Lines. By P. ZEEMAN. (Macmillan's Science Monographs.) London: Macmillan and Co., Ltd. 1913. Pp. xvi + 219 + viii plates.

Since the discovery by Zeeman in 1896 of the resolution of spectrum lines in the magnetic field, works have appeared at intervals which summarized the development of the subject to the date of publication. Each of these has been needed when it appeared, partly by reason of differences in treatment by the several authors, but chiefly because of the continuous output of new matter, both on the experimental and theoretical sides; so that an author, by the time his book was off the press, would welcome an opportunity to add numerous footnotes or an extensive appendix.

The investigation of the Zeeman effect during these seventeen years impresses one as having been very ably conducted. The immediate development of the elementary theory by Lorentz gave the phenomenon the place in relation to the theories of light and of electricity which it has ever since maintained. Although the demands on instrumental equipment are severe, the rich field and the close connection with theory caused investigations to be taken up in many laboratories and the requirements have greatly stimulated the development of optical methods. In some cases, theory has predicted a result which at once appeared when the experiment was tried. On the other hand, if one compares the original explanation of the normal triplet with the involved mathematical treatments employed to account for the complex resolutions, the pressure exerted on the theorists by the laboratory results is quite apparent. The development of the theory, however, has been one of growth from a beginning still regarded as sound.

In the book under review, Professor Zeeman

has given us an account, simple in language, largely historical in arrangement, and occasionally touched with personal reminiscence, which records in a highly attractive manner the main features of the investigations started by his discovery. It is in keeping with the title and with the series of monographs to which this book belongs that the author devotes his closest analysis to those features of the phenomenon which have been studied in his own laboratory. This involves the correlation of his results with those of others on these subjects, but other important lines of investigation, such as the application to spectral series, are not omitted.

The first chapter is devoted to the instrumental means employed in the study of the Zeeman effect, especially as regards the efficiency of different spectroscopes in giving the high resolving power required. Emphasis is laid on the three requirements of great resolving power, high magnetic field-strength, and sharpness of spectrum lines for the best results in this work. At the close of the chapter we are reminded of what has occurred to many investigators, that we are near the limit of field strength to be obtained from an iron-cored magnet, and that the hope of great advance, both as to intensity and uniformity of field, lies in the use of a large solenoid. Although the construction of this would require a larger expenditure than has ever been devoted to a single line of physical research, the certainty of the results would seem to make the adoption of the method only a question of time.

The early investigations on emission spectra and the derivation of e/m from the separation of the normal triplet are treated in the second chapter, and the author passes next to the "inverse effect," or the magnetic resolution of absorption lines. This branch of the study must be regarded as still in a preliminary stage. A decided stimulus has been given to the examination of the inverse effect by the discovery of the magnetic field in sun-spots, and much important work, described in a later chapter, has been done by Zeeman himself. The methods are quite different from

those employed with emission spectra and the difficulties arise from peculiar causes. The close analogy of the effects with those of bright line spectra is well worked out, however, and we must admire the skill shown in tracing out the action of polarization of the white light and varying density of the absorbing vapor in altering the effects.

In the following chapters, several branches of investigation of the Zeeman effect are considered in turn. A short account is also given of the related phenomena of magnetic rotation in vapors and magnetic double refraction. The study of multiple resolutions is traced, from the observation that all lines are not normal triplets to the profoundly significant relation of the commensurability of the components given by Runge. Dissymmetries in the resolution and a shift of the middle component are features of the later study which are reviewed by Zeeman.

A chapter on solar magneto-optics summarizes the results of the study of the magnetic field of sun-spots by Hale and of his first observations on the general field of the sun. This is followed by a chapter describing the important experiments of Zeeman and Winawer on the inverse effect in directions inclined to the field. Undertaken because of its application to the solar magnetic effects, this work has been carried out with the highest skill and resourcefulness. Results have been obtained which undoubtedly bear closely on the solar phenomena and can be applied when sun-spots are again in evidence.

The closing chapter of the monograph, on the relation between magnetic resolution and the chemical nature of the elements, may be characterized as a statement of unsolved problems. In it we are made to feel how young the subject of magneto-optics is, and that in some directions the considerable mass of experimental material has served to show that a connection with other departments of knowledge exists but leaves the nature of the relation highly obscure. Thus, the relation between magnetic resolution and arrangement of the lines in series is clear only for a few elements having low atomic weights and few

lines in their spectra. The fact that a series line which is double with no field may change to a simple triplet in the field is an anomaly which affects the whole question of the connection with series relations. There is probably a fundamental relation between magnetic resolution and the pressure effect, but no close correspondence in detail.

A summary of the leading features of several atomic theories and a highly useful bibliography, giving the entire literature arranged according to year of publication, close a volume which will be appreciated by every student of the subject.

ARTHUR S. KING

MT. WILSON SOLAR OBSERVATORY

Mountains, their Origin, Growth and Decay.
By JAMES GEIKIE, LL.D., F.R.S., etc.
Edinburgh, Oliver and Boyd. 1913. Pp. 311, 80 Pl., 57 Figs. in text.

This volume contains in systematic form the substance of various contributions made by Professor Geikie during the last twenty years, supplemented with much new matter. The author recognizes two classes of mountains, original or tectonic, and subsequent or relief.

Tectonic mountains are due to accumulation or deformation; the former includes the various types of volcanoes as well as glacial and æolian hills; all of which grow by additions to the outside; the latter includes folded, dislocation and laccolith forms, all due to crustal disturbance. The study of tectonic mountains occupies by far the greater part of the work, which is intended to be a non-technical presentation of the subject. Such matters as glacial action, metamorphism, types and causes of folding, structure of the Alps, origin of ocean "deeps" are discussed as simply and easily as though they were familiar topics of every-day conversation. Certainly, this mode of treatment shows that exact scientific method does not require much aside from ordinary language, for one knowing only the general principles of physics and geology can grasp the situation so as to appreciate the difficulties with which an investigator must contend as

well as the great opportunity for erroneous conclusions. The geologist, finding the statements exact, can not complain because the presentation is such as to be attractive to the layman. Subsequent mountains, being merely relics of former highland, receive briefer treatment, and the discussion is confined chiefly to consideration of the various destructive agencies and their action upon the rocks and types of structure.

As one should expect in a work intended mostly for "home consumption," full share of the space is given to such Scottish and English areas as afford proper illustrations; but in this, as in earlier works by Professor Geikie, there is ample evidence of intimate acquaintance with conditions elsewhere, and he has levied contributions upon all parts of the world. The plates, reproductions of photographs from many lands, are of unusual excellence and the text is full of suggestive matter for the geologist in every land.

Some portions of the work are deliciously controversial; the consideration of phenomena in the Pacific basin is thorough and the argument against explanations offered by Suess is put very strongly; some American geologists will regard the opinions respecting isostasy as not altogether orthodox, and several continental geologists will feel convinced that the author does not know so much about Alpine structure as they do. But all, whether accepting or opposing his conclusions, will agree that the tone of his presentation is judicial throughout, as benefits one who has made direct study in a great part of Europe and whose familiarity with the literature is equalled by that of few other geologists.

JOHN J. STEVENSON

The Indigenous Trees of the Hawaiian Islands. By JOSEPH F. ROCK, botanist of the College of Hawaii; consulting botanist, Board of Commissioners of Agriculture and Forestry, Territory of Hawaii. Issued June 26, 1913. With two hundred and fifteen photo-engravings. Published under patronage. Honolulu, T. H. 1913. Large octavo. Pp. viii + 518.

This stately volume includes descriptions of two hundred and twenty-five species of trees which are natives of the Hawaiian Islands. The author tells us in his preface that it had "long been the writer's desire to give to the public a volume on the native trees of Hawaii," so that this work is the result of a protracted study of the interesting vegetation of these isolated islands, and as a consequence is much more authoritative and complete.

The introduction, of 87 pages, gives "a more or less detailed description of all the floral regions, and their plant associations found in this island group, not being restricted to trees alone, but embracing the whole plant covering." In it we are first given a tabular enumeration of the botanical regions, as follows:

1. Strand vegetation.
2. Lowland region (merging into 3).
 - (a) Dry region.
 - (b) Wet region.
3. Lower forest region.
 - (a) Windward side.
 - (b) Leeward side.
4. Middle forest region.
 - (a) Dry region.
 - (b) Semi-dry region.
 - (c) Wet region.
 - (d) *Kipukas* (small areas of black, fertile soil in dry regions with no trace of lava, richest in species).
5. Bog region.
6. Upper forest region.

These are described at some length, and are illustrated by many good photo-engravings. On the largest of the islands (Hawaii) the mountains reach elevations of 8,273 feet, 13,675 feet and 13,823 feet, so that there are wide climatic ranges from tropical heat to "almost perpetual snow." Indeed the author sums up his statement in the sentence, "from a phytogeographic standpoint the island of Hawaii offers the most interesting field in the Pacific."

Coming now to the systematic part of the book one finds that no less than forty-five families of plants are represented by species of trees. And yet with all the variety that this implies there is scarcely a familiar genus in

the whole book. There are two tree ferns, of the genus *Cibotium*, one (*C. menziesii*) reaches a total height of 26 feet and its stem often has a diameter of three feet. Monocotyledons are represented by a *Pandanus*, eleven palms (*Pritchardi* and *Cocos*) and a *Dracaena*. In the Dicotyledons one finds many unfamiliar genera in familiar families: as *Trema* (Ulmaceae), *Urera* and *Pipturus* (Urticaceae), *Nototrichium* and *Charpentiera* (Amaranthaceae), *Broussaisia* (Saxifragaceae), *Colubrina* (Rhamnaceae), *Jambosa*, *Syzygium*, and *Metrosideros* (Myrtaceae), *Pteralyzia*, *Ochrosia* and *Rauwolfia* (Apocynaceae), *Clermontia* and *Cyanea* (Campanulaceae), *Dubautia*, *Railardia*, and *Hesperomannia* (Compositae). On the other hand one finds, also, *Artocarpus* (Moraceae) the well-known "Breadfruit tree"; *Pittosporum* (Pittosporaceae), of which there are twelve species, several of which are more than twenty feet high; *Acacia* and *Sophora* (Leguminosae); *Xanthoxylum* (Rutaceae); *Euphorbia* (Euphorbiaceae), two species of trees from 15 to 25 feet in height; *Rhus* (Anacardiaceae); *Ilex* (Aquifoliaceae), one tree of 20 to 40 feet in height; *Hibiscus* (Malvaceae), including trees 20 to 30 feet in height; *Sideroxylon* (Sapotaceae), some 50 to 60 feet high; *Osmanthus* (Oleaceae), sixty feet high; *Solanum* (Solanaceae) a small tree, 15 to 20 feet high. Many of the trees bear foliage of such a structure as to hide completely their botanical relationship.

Among the notable trees is the koa (*Acacia koa*), "one of our most stately trees." "It is perhaps the most valuable tree which the islands possess, as it is adapted for construction as well as for cabinet work. The koa reaches a height of more than 80 feet in certain localities, with a large trunk vested in a rough, scaly bark of nearly an inch in thickness." Another tree (*Pisonia umbellifera*) possesses so soft a stem that "trunks of a foot in diameter can be felled with one stroke of the axe."

The largest family, so far as the tree species are concerned, is Rutaceae (32 sp.), followed closely by Rubiaceae (31 sp.), and then Campanulaceae (15), Araliaceae (14),

Pittosporaceae (12), Palmaceae (11), Myrsinaceae (11), and Malvaceae (10).

At the end of the volume there is a good index to the scientific names, followed by one of the Hawaiian and few English names.

CHARLES E. BESSEY

THE UNIVERSITY OF NEBRASKA

Science from an Easy Chair. Second series.

By SIR RAY LANKESTER. New York, Henry Holt and Company. 1913. Pp. 412.

In his chapter on Museums, Sir Ray Lankester deplores the fact that so many are "mere enlargements of the ancient collector's 'cabinet of rare and curious things,' brought together and arranged without rhyme or reason." His book, dealing in one small volume with such diverse matters as Kisses, Ferns, Glaciers, Elephants and Tadpoles, might possibly be described in similar terms; yet it is by no means without merit. It is a significant and interesting fact that a zoologist of the first rank, retiring from the directorship of the British Natural History Museum, should think it worth his while to contribute weekly articles on scientific subjects to a daily paper, regularly for a period of five years. It is no less significant that this paper (the *Daily Telegraph*) should be willing to print them as they stand, popular in form, but dealing in many cases with technical matters which require close attention in order to be understood. The book before us consists of a selection from this newspaper series, with some revision and expansion, and a number of illustrations. It possesses the original journalistic tone, and consists essentially of well-written dissertations on matters familiar to specialists, but, for the most part, new to the general public. I have read the greater part of it with pleasure and interest, and, while different chapters will appeal to different people, few can fail to find something of value. Some of the essays, as those on Food and Cookery and Misconceptions about Science, reflect so strongly the author's prepossessions that they naturally arouse a combative spirit in those of a different temper. Here and there, expressions have crept in which the author would scarcely de-

fend in cold blood; thus (p. 19) "even the destructive bacteria which are killed by the sun probably enjoy an exquisite shudder in the process which more than compensates them for their extinction"; and (p. 344) "every step which he [the house-fly] takes he plants a few dozen microbes, which include those of infantile diarrhoea, typhoid and other prevalent diseases,"—a gross exaggeration in a chapter which very properly calls attention to the great harm done by flies as carriers of bacteria.

The time has certainly come for scientific men in America to attack the problem of scientific journalism in an organized and deliberate manner. The individual naturalist is more or less helpless. When I was curator of the museum in Jamaica I contributed weekly articles to the newspapers of Kingston, which printed them as written, and even illustrated them when requested. These articles interested a good many people and were the cause of many visits and contributions to the museum. In Colorado I have tried the same thing, and given it up in despair. The papers will not print things accurately or in full, and will often supply headlines of the most ridiculous kind. Here is a typical incident. A friend of mine shot a large eagle and measured it from tip to tip of the wings. Thinking the matter of interest, he handed in the item to a daily paper. The editor, with the best of intentions in the world, added a foot to the measurement, with the result that my friend appeared to those who knew anything of eagles a remarkable liar! These troubles are not confined to the wild and woolly west. Even the *Outlook*, certainly one of our best-edited journals, recently published an article on A. R. Wallace which contained in the first column a number of errors concerning the best-known facts of his life.

It is not true, of course, that the newspapers *always* select incompetent writers on scientific subjects, or *always* distort accurate information communicated to them; but if they are to be the means of enlightening the public concerning the discoveries of science, they must *never* do these things, except

through such unfortunate accidents as can not perhaps wholly be avoided. One can not write to the papers if the chances are one in five or ten that one will be exhibited as a fool or liar, and the public misled as to the facts.

T. D. A. COCKERELL

SPECIAL ARTICLES

A NOTE ON SEX DETERMINATION¹

OF the many hypotheses that have been advanced to explain the determination of sex, one group seeks to show that in bilateral animals the sex of the offspring is dependent upon the right or left source of the effective genital element in that right glands produce offspring of one sex, left glands those of the other. Such a general theory may be applied, of course, to either the ovary or the testis. Thus Seligson (1895)² formulated the hypothesis that in mammals the right ovary gives rise to eggs that produce male offspring, the left to eggs that produce female offspring.

In collecting a body of data to show the relation of the size of litters to the number of nipples in swine (Parker and Bullard, 1913),³ certain facts appeared which have a bearing on such hypotheses. The records brought together in this connection included the position that the young pigs occupied in the uterus and their sex. In reasonably large litters it was therefore possible to make a rough comparison of the products of one ovary with those of the other by contrasting the young pigs in one horn of the uterus with those in the other. The possibility of the migration of an egg from one side of the body to the other could not be excluded, but to reduce to a minimum the effect of this on the statistics and to make the comparison as striking as possible, the

¹ Contributions from the Zoological Laboratory of the Museum of Comparative Zoology at Harvard College, No. 245.

² Seligson, E., "Zur Bestimmung und Entstehung des Geschlechts," *Centralbl. für Gynäkol.*, Bd. 19, pp. 590-595, 1895.

³ Parker, G. H., and C. Bullard, "On the Size of Litters and the Number of Nipples in Swine," *Proceed. Amer. Acad. Arts and Sci.*, Vol. 49, pp. 397-426, 1913.

whole contents of horns were not compared, but the pairs of animals next the right and the left ovaries were contrasted, so far as their sexes were concerned, with the pairs at the junction of the horns, the presumption being that the pure products of each ovary would occur most frequently next that organ and the mixed products of the two ovaries midway between them. The details thus brought together are shown in the following table.

TABLE

This table shows the frequency of occurrence of pairs of unborn pigs of various combinations of sexes at the division of the horns of the uterus, next the right ovary, and next the left ovary.

Composition of Pairs		♂ ♂	♀ ♀	♂ ♀
Observed frequencies	At division of horns	252	240	456
	Next right ovary	228	209	434
	Next left ovary	216	208	447
Percentage frequencies	At division of horns	26.6—	25.3+	48.1+
	Next right ovary	26.2—	24.0—	49.8+
	Next left ovary	24.8—	23.9—	51.3+

It is fair to assume that at the division of the horns of the uterus the offspring are likely to be as often from one ovary as from the other. If in the whole population the males and females are equally abundant, three classes of pairs would be expected to occur and in the following proportions: 25 per cent. of the pairs would be composed of two males; 25 per cent. of two females; and 50 per cent. each of a male and a female. That this condition is very nearly realized is seen from the table, where it will be observed that the pairs of males are present to the extent of 26.6— per cent., the females 25.3+ per cent. and the pairs of the two sexes combined 48.1+ per cent. The fact that the table shows a few more pairs of males than females is due to the condition of the population as a whole, in which the males outnumber the females by 1,026 to 1,000. This slight digression from equality also has its effect on the relation of the numbers of pairs composed of both sexes to those of one sex only, but the total number of records is probably too small to yield very smooth results in this respect.

If, as Seligson maintained, the right ovary gives rise to male and the left to female offspring, the pairs of pigs next the right ovary ought to be predominantly males and those next the left predominantly females. That such is not the case is seen at once from the table, where it is shown that pairs composed of two males or of two females occur in about the same proportions next the right ovary that they do next the left, a proportion that is very close to that occurring at the division of the horns of the uterus. These statistics, therefore, give no support to hypotheses, such as Seligson's, according to which the eggs from the ovary of one side of the body produce offspring of one sex only.

Although the sex of the offspring is thus shown not to be correlated with the side of the body from which the egg that gave rise to the young came, it might be supposed that in any female a given ovary would always produce offspring of the same sex. In that case we should expect to find the great majority of pairs of young next the ovaries to be either both males or both females. But, as the table shows, there are almost as many pairs composed of one male and one female next the ovaries as there are at the division of the horns. Hence we may conclude that in the pig the ovaries by virtue of their position in one or other half of the maternal body exert no influence on the sex of the offspring, but that each ovary produces eggs which may give rise to either male or female offspring. This conclusion is in line with such experimental work as that of Doncaster and Marshall (1910),⁴ and of King (1911)⁵ on albino rats, according to which a single ovary, after the removal of its mate, can give rise to eggs which produce males and females.

THE FEDERATION OF AMERICAN SOCIETIES FOR EXPERIMENTAL BIOLOGY

FOR a number of years the members of the Physiological, the Biochemical and the Pharmacological Societies have felt the desirability of a closer cooperation of these and other biological societies, especially as regards the annual scientific meetings. At the meeting in Chicago in 1907 the Physiological Society appointed a committee on policy with instructions to report at the next annual meeting. At the meeting in Baltimore in 1908 the chairman of this committee, Dr. A. P. Mathews, presented a plan for reorganizing all the present biological societies into a general Biological Society. The plan involved a change in policy and in the character of the membership of at least some of the societies, and an extensive venture in the publication of scientific journals. These features were not endorsed by the society, but the general plan of affiliation of all the biological societies was favorably received and Dr. Mathews was appointed delegate from the Physiological Society to confer with delegates from the other biological societies to this end. This committee does not appear to have made any progress.

At the meeting in Cleveland in 1912, the Physiological, Biochemical and Pharmacological Societies appointed committees to propose plans for affiliation. The committee consisted of Drs. Meltzer, Lee and Cannon from the Physiological Society, Drs. Lusk, Gies and Wells from the Biochemical Society and Drs. Sollmann, Loevenhart and Auer, from the Pharmacological Society. This committee submitted the following plan:

1. That the three societies affiliate under the name of the Federation of American Societies for Experimental Biology.
2. That the presidents and secretaries of the three societies constitute the executive committee of the federation.
3. That programs of the annual meetings be printed under one cover, and that the secretaries confer and adjust the papers with the view of the greatest coordination.
4. That a common meeting place of the federation with the anatomists, zoologists and naturalists is desirable.

The annual meeting in Philadelphia, December 28-31, 1913, was arranged by the executive committee of the federation according to the above plan. Those present at the meeting were in substantial agreement that it was a success. At this

meeting the plan of the organization committee was ratified by the three societies and the Society for Experimental Pathology joined the federation. This brings the total membership of the federation up to about 450.

The distinctive feature of the federation plan is the cooperation and coordination in the essential things, with no interference with the individuality of the societies. This cooperation is certainly desirable between all the biological societies, and we believe the federation plan can and ought to be extended in that direction. We believe it will increase the efficiency of the societies as agencies for the promotion of research and dissemination of truth.

At the first executive meeting of the federation, December 31, 1913, the following declaration on the subject of animal experimentation was unanimously adopted:

1. We, the members of the Federation of American Societies for Experimental Biology—comprising the American Physiological Society, the American Society of Biological Chemists, the American Society for Pharmacology and Experimental Therapeutics and the American Society for Experimental Pathology,—in convention assembled, hereby express our accord with the declaration of the recent International Medical Congress and other authoritative medical organizations, in favor of the scientific method designated properly animal experimentation but sometimes vivisection.

2. We point to the remarkable and innumerable achievements by means of animal experimentation in the past in advancing the knowledge of biological laws and devising methods of procedure for the cure of disease and for the prevention of suffering in human beings and lower animals. We emphasize the necessity of animal experimentation in continuing similar beneficent work in the future.

3. We are firmly opposed to cruelty to animals. We heartily support all humane efforts to prevent the wanton infliction of pain. The vast majority of experiments on animals need not be and, in fact, are not accompanied by any pain whatever. Under the regulations already in force, which reduce discomfort to the least possible amount and which require the decision of doubtful cases by the responsible laboratory director, the performance of those rare experiments which involve pain is, we believe, justifiable.

4. We regret the widespread lack of informa-

tion regarding the aims, the achievements and procedures of animal experimentation. We deplore the persistent misrepresentation of these aims, achievements and procedures by those who are opposed to this scientific method. We protest against the frequent denunciations of self-sacrificing, high-minded men of science who are devoting their lives to the welfare of mankind in efforts to solve the complicated problems of living beings and their diseases.

Executive Committee of the Federation for the Year 1914.—W. B. Cannon, A. J. Carlson, the Physiological Society; G. Lusk, P. A. Shaffer, the Biochemical Society; T. Sollmann, J. Auer, the Pharmacological Society; R. M. Pearce, G. H. Whipple, the Pathological Society; G. Lusk, *Chairman*; P. A. Shaffer, *Secretary*.

Secretary of the Executive Committee, 1913

UNIVERSITY OF CHICAGO,

January 10, 1914

THE AMERICAN SOCIETY OF BIOLOGICAL CHEMISTS

THE eighth annual meeting of the American Society of Biological Chemists was held at Philadelphia on December 29, 30, 31, 1913, in affiliation with the American Physiological Society and the American Society for Pharmacology and Experimental Therapeutics, as the first meeting of the Federation of American Societies for Experimental Biology. The meetings of the society were well attended and highly successful. The joint meetings, as in past years, were of great interest to the members of all of the societies, and these, together with the cooperation in the arrangement and printing of programs, emphasized the advantages of the closer relations between the societies made permanent by the formation of the federation. The scientific programs are appended.

First Session.—December 29, 9 A.M., at the Jefferson Medical College. Joint session with the American Physiological Society and the American Society for Pharmacology and Experimental Therapeutics, as the first session of the federation. Presiding officer, S. J. Meltzer, president of the American Physiological Society and chairman of the federation.

Presidential address, "Theories of Anesthesia," by S. J. Meltzer.

"Phlorhizin Glycosuria before and after Thyroidectomy," by Graham Lusk.

"Studies in Diabetes: (1) The Effect of Different Compounds on Glycogenesis"; (2) "The Mechanism of Antiketogenesis," by A. I. Ringer and E. M. Frankel (by invitation).

"Some Problems of Growth: (a) The Capacity to Grow; (b) The Role of Amino Acids in Growth," by L. B. Mendel and T. B. Osborne.

"Further Studies in the Comparative Biochemistry of Purine Metabolism," by Andrew Hunter.

"Changes in Fats during Absorption," by W. R. Bloor.

"Immunization against the Anti-coagulating Effect of Leech Extract," by Leo Loeb. (By title.)

"Anaphylaxis in the Cat and Opossum," by C. W. Edmunds.

"Vivification; Report on Preliminary Results," by J. J. Abel, L. G. Rowntree and B. B. Turner.

"A Method of Dialyzing Normal Circulating Blood and Some of Its Applications," by C. L. V. Hess (by invitation) and H. McGuigan.

"A Biological Test for Iodine in the Blood," by A. Woelfel and A. L. Tatum (by invitation).

"Further Studies of the Excretion of Acids," by L. G. Henderson and W. W. Palmer (by invitation).

Second Session.—December 29, 2:30 P.M. at the Jefferson Medical College. Presiding officer, President A. B. Macallum.

Presidential address, "The Physics of Secretion and Excretion," by A. B. Macallum.

"The So-called Vegetable Proteoses and their Biological Reactions," by H. G. Wells and T. B. Osborne.

"Some Anaphylactic Reactions," by H. C. Bradley.

"The Mode of Action of Soy Bean Urease," by D. D. Van Slyke and Glen E. Cullen (by invitation).

"Glycol Aldehyde in Phlorhizinized Dogs," by R. T. Woodyatt. (By title.)

"Trikesol as a Substitute for Toluene in Enzyme Work," by P. A. Kober and S. S. Graves (by invitation).

"A Study of the Metabolism in Osteitis Deformans," by J. C. DaCosta, E. H. Funk, Olaf Bergeim (by invitation) and P. B. Hawk.

"Metabolism in Diabetes Insipidus," by S. Bookman. (By title.)

"Some Metabolic Effects of Bathing in the Great Salt Lake," by H. I. Mattill (by invitation) and H. A. Mattill. (By title.)

"Absorption of Antitoxin from Solutions Containing Different Percentages of Protein,"¹ by W. H. Park, E. J. Banzhaf and L. W. Famulener.

Third Session.—December 30, 9 A.M., at the University of Pennsylvania. Presiding officer, President A. B. Macallum.

"The Carbohydrate Tolerance of Feeble-minded Children, especially of the Mongolian Type," by A. W. Peters and M. E. Turnbull (by invitation).

¹ Transferred from the Pharmacological Society.

"Protein Metabolism in Individuals with Exfoliative Conditions of the Skin," by A. I. Ringer and G. W. Raiziss (by invitation).

"The Oxygen Requirements of Shell Fish," by P. H. Mitchell.

"The Metabolic Relationship of the Acetone Bodies," by W. McK. Marriott.

"Phenomena of Narcosis of Leaves of the Wild Indigo (*Baptisia tinctoria*) and Consequent Production of a New Phenol," by E. D. Clark. (By title.)

"A Hitherto Unknown Constituent of Nerve Cells," by A. B. Macallum and J. B. Collip (by invitation).

"A Note on the Chemical Constituents of the Cerebrospinal Fluid in Certain Cases of Insanity," by H. M. Adler and B. H. Ragle (by invitation). (By title.)

"On the Estimation of Minute Quantities of Phosphorus," by A. E. Taylor and C. W. Miller (by invitation).

"Formation of Glucose from Citric Acid in Diabetes Mellitus and in Phlorhizin Glycosuria," by I. Greenwald.

"Further Results upon the Electrolysis of Peptides and Amino Acids," by J. P. Atkinson. (By title.)

"Researches on the Heptoses," by George Peirce (by invitation).

"The Nerve Control of the Thyroid Gland," By C. G. Fawcett (by invitation) and J. A. Rahe (by invitation). (Presented by S. P. Beebe.)

Fourth Session.—December 30, 2 P.M., at the medical laboratory of the University of Pennsylvania. Joint meeting with the American Physiological Society and the American Society of Pharmacology and Experimental Therapeutics. Presiding officer, President S. J. Meltzer.

Presentation of Demonstrations

The Influence of the Vagi on Renal Secretion, by R. G. Pearce.

Stimulation of the Semi-circular Canals, by F. H. Pike.

Demonstration of Vividiffusion, by J. J. Abel, L. G. Rowntree and B. B. Turner.

The Determination of Blood Sugar, by P. A. Shaffer.

Intestinal Peristalsis in *Homarus*, by F. R. Miller.

Methods for Studying the Pharmacology of the Circulation, by C. Brooks.

The Contour of the Intraventricular and the Pulmonary Arterial Pressure Curves by Two New Optically Recording Manometers, by C. J. Wiggers.

Some Time-saving Laboratory Methods, by C. C. Guthrie.

A Graphic Method for Recording the Coagulation of Blood, by W. B. Cannon and W. L. Mendenhall (by invitation).

Some Mutual Relations of Oxalates, Salts of Magnesium and Calcium; Their Concurrent and Antagonistic Actions, by F. L. Gates and S. J. Meltzer.

A Method of obtaining Successive Contrast of the Sensations of Hunger and Appetite, by A. J. Carlson.

Further Observations on the Pyramidal Tracts of the Raccoon and Porcupine, by S. Simpson.

A New Apparatus for Demonstration of the Dioptries of the Eye and the Principles of Ophthalmoscopy and Retinoscopy, by A. Woelfel.

Simple Experiments on Respiration for the Use of Students, by Y. Henderson.

Convenient Modification for Venous Pressure Determinations in Man, by R. D. Hooker.

Device for Interrupting a Continuous Blast of Air, Designed Especially for Artificial Respiration, by R. A. Gesell and J. Erlanger.

A Simple Liver Plethysmograph, by C. W. Edmunds.

An Artificial Circulation Apparatus for Students, by W. P. Lombard.

A Simplified and Inexpensive Oxadase Apparatus, by H. H. Bunzel.

An Improved Form of Apparatus for Perfusion of the Excised Mammalian Heart, by M. Dessbach.

Fifth Session.—December 31, 9 A.M., at the University of Pennsylvania. Presiding officer, President A. B. Macallum.

"Biological Oxidizability and Chemical Constitution," by H. H. Bunzel.

"Albuminuria Following Phenolphthalein Ingestion," by J. L. Hydrich (by invitation).

"The Determination of Fats in Small Amounts of Blood," by W. R. Bloor.

"Creatine Determination in Muscle," by L. Baumann.

"A Respiration Chamber for Small Animals," by A. C. Kolls (by invitation) and A. S. Loevenhart.

"A Respiration Incubator for the Study of Metabolism in New-born and Prematurely Born Infants," by J. R. Murlin.

"The Specific Role of Foods in Relation to the Composition of the Urine," by N. R. Blatherwick (by invitation).

"Creatinine and Creatine-free Foods," by Rita K. Chestnut (by invitation). (Presented by A. B. Macallum.)

"Experimental Hydrochloric Acid Intoxication," by S. Bookman. (By title.)

"The Effects of Water-gas Tar on Oysters," by P. H. Mitchell. (By title.)

"The Effect of Glucose on Autolysis: A Possible Explanation of the Protein-sparing Action of Carbohydrates" (preliminary note), by P. A. Shaffer.

"The Passage of Organic Substances from Plant to Medium," by M. X. Sullivan. (By title.)

"Studies on Chicken Fat VI. The Factors Influencing the Acidity of the Crude Fat," by M. E. Pennington, J. S. Hepburn (by invitation) and E. L. Connolly (by invitation).

By Title:

"The Influence of Restricted Rations on Growth," by E. B. Hart and E. V. McCollum.

"Production of Ammonia by Herbivora as a Protection Against Acidosis," by E. B. Hart and E. V. Nelson (by invitation).

"The Influence of Restricted Rations on Reproduction," by E. B. Hart, E. V. McCollum and H. Steenbock.

"Further Studies on the Quantitative Chemical Composition of Urinary Calculi," by J. Rosenbloom.

"On the Quantitative Chemical Composition of Gall Stones," by J. Rosenbloom.

"Metabolism Studies in a Case of Family Periodic Paralysis," by J. Rosenbloom and T. Diller (by invitation).

"Calcium Metabolism in Thyroparathyroidectomy," by F. T. Stewart (by invitation), Olaf Bergeim (by invitation), and P. B. Hawk.

"Variations in the Hydrogen Ion Concentration of the Urine of Man Accompanying Fasting and the Low and High Protein Regeneration Periods," by P. E. Howe and P. B. Hawk.

The following papers submitted in the American Society of Biological Chemists were transferred with the authors' consent and in accordance with the principles of the Federation, to the program of one of the other societies:

Presented before the American Physiological Society:

"The Maximum Surface Tension in Striated Muscle," by W. N. Berg. (By title.)

"Sources of Surface Tension in Striated Muscle," by W. N. Berg.

"Transfusion of Blood in Severe Diabetes Mellitus," by R. T. Woodyatt and B. O. Raulston (by invitation).

Presented before the American Society for Pharmacology and Experimental Therapeutics:

"The Production of Glycosuria by Zinc Salts," by W. Salant and M. Kahn.

"Further Observations of Caffeine Glycosuria," by W. Salant and M. Kahn.

"Studies Upon the Long-continued Feeding of Saponine," by C. L. Alsberg and C. S. Smith.

New Members.—Dr. Shiro Tashiro, University of Chicago, Chicago, Ill.; Dr. E. K. Marshall, Jr., Johns Hopkins Medical School, Baltimore, Md.; Professor R. S. Lillie, Clark University, Worcester, Mass.; Dr. K. G. Falk, Harriman Research Laboratory, Roosevelt Hospital, New York; Dr. F. C. Cook, Bureau of Chemistry, Department of Agriculture, Washington, D. C.; Dr. W. H. Eddy, Columbia University, New York; Professor R. F. Ruttan, McGill University, Montreal, Canada; Dr. H. B. Lewis, University of Pennsylvania, Philadelphia, Pa.; Dr. C. J. West, Rockefeller Institute, New York; Dr. E. C. Kendall, St. Luke's Hospital, New York; Dr. G. W. Raiziss, Polyclinic Hospital, 1818 Lombard Street, Philadelphia Pa.; Professor A. D. Hirschfelder, University of Minnesota, Minneapolis, Minn.

Officers Elected.—The following officers were elected for the year 1914:

President: Graham Lusk.

Vice-president: C. L. Alsberg.

Secretary: P. A. Shaffer.

Treasurer: D. D. Van Slyke.

Additional Members of the Council: J. J. Abel, A. B. Macallum, T. B. Osborne.

Nominating Committee.—S. R. Benedict, H. S. Bradley, Otto Folin, W. J. Gies, J. H. Kastle, J. B. Leathes, P. A. Levene, L. B. Mendel, H. G. Wells.

The society voted its formal approval of the establishment of the Federation of American Societies for Experimental Biology, comprising the American Physiological Society, American Society of Biological Chemists and the American Society for Pharmacology and Experimental Therapeutics. The society also voted in favor of admitting to the federation the newly organized American Society for Experimental Pathology.

A unanimous vote of thanks was extended by the society to the individual members of the "local committee," to the University of Pennsylvania and to the Jefferson Medical College for the hospitality which the society enjoyed.

The following members were present at one or more of the sessions of the meetings: J. J. Abel, C. L. Alsberg, S. Amberg, L. Baumann, S. P. Beebe, W. N. Berg, W. K. Bloor, H. C. Bradley, H. H. Bunzel, R. Burton-Opitz, E. D. Clark, F. C. Cook, H. D. Dakin, Willey Denis, W. H. Eddy, Otto Folin, W. J. Gies, I. Greenwald, Shinkishi Hatai, R. A. Hatcher, P. B. Hawk, L. J. Henderson, P. E. Howe, W. H. Howell, R. Hunt, A. Hunter, N. W. Janney, W. Jones, I. S. Kleiner, P. A. Kober, J. B. Leathes, J. Loeb, A. S. Loevenhart, Graham Lusk, A. B. Macallum, J. J. Macleod, W. deB. MacNider, W. McK. Marriott, E. K. Marshall, J. Marshall, E. V. McCollum, F. H. McCrudden, H. McGugan, L. B. Mendel, P. H. Mitchell, J. R. Murlin, V. C. Myers, T. B. Osborne, A. W. Peters, G. W. Raiziss, A. N. Richards, A. I. Ringer, E. W. Rockwood, L. G. Rowntree, Wm. Salant, F. H. Scott, P. A. Shaffer, T. Sollmann, Shiro Tashiro, A. E. Taylor, F. P. Underhill, D. D. Van Slyke, C. Voegtlin, G. B. Wallace, H. G. Wells, R. T. Woodyatt.

Abstracts of the papers will be published in the *Journal of Biological Chemistry*.

P. A. SHAFFER,
Secretary

WASHINGTON UNIVERSITY
MEDICAL SCHOOL,
ST. LOUIS, MISSOURI

THE AMERICAN ASSOCIATION OF ECONOMIC ENTOMOLOGISTS

THE 26th annual meeting of the association was held in the Atlanta Medical College, Atlanta, Ga., December 31, 1913, to January 2, 1914, under the presidency of Professor P. J. Parrott, Geneva, N. Y.

The report of the secretary showed that the association was making a healthy growth and that the *Journal of Economic Entomology* was gradually increasing in circulation and that its financial condition was satisfactory.

Prior to the meeting arrangements were made for the incorporation of the association. This was brought about and the association is now incorporated as a membership corporation under the laws of the District of Columbia.

During the meeting the association considered the possibility of securing the publication of a bibliography of economic entomology and a committee was appointed to take charge of assembling the references required, and to investigate the possibilities of publishing this useful work.

Thirty-four new members were elected to the association and the following officers were elected for the ensuing year:

President—Dr. H. T. Fernald, Amherst, Mass.

First Vice-president—Professor Glenn W. Herick, Ithaca, N. Y.

Second Vice-president—Dr. W. E. Britton, New Haven, Conn.

Third Vice-president—Professor Wilmon Newell, College Station, Texas.

Secretary—A. F. Burgess, Melrose Highlands, Mass.

It was voted to hold the next meeting in conjunction with that of the American Association for the Advancement of Science at Philadelphia next December.

The section on apiary inspection met on January 1 at 10:30 A.M., and was presided over by Professor Wilmon Newell, College Station, Texas. In the absence of the secretary, Mr. N. E. Shaw, Columbus, Ohio, was elected to act as secretary. Several papers were presented and a general discussion followed concerning the apiary inspection work which is being carried on by the different states. At the close of the session the above-mentioned officers were elected for the ensuing year.

The section on horticultural inspection was presided over by Professor E. L. Worsham, Atlanta, Ga., and Professor J. G. Sanders, Madison, Wis., as secretary. The meeting was called to order at 1:30 P.M., January 1, and an adjourned meeting was held at 7 P.M. in the parlors of the Ansley Hotel. A full program of papers was presented at this meeting and many subjects of interest to horticultural inspectors were considered and discussed. One of the most important matters brought before the section was the consideration of a uniform

nursery inspection law and more definite standards for inspection of nursery stock, which passes into interstate commerce. The meeting adjourned at 8 P.M., and the following officers were elected to serve for the ensuing year: Dr. W. E. Britton, New Haven, Conn., *Chairman*; Professor J. G. Sanders, Madison, Wis., *Secretary*. At the close of this meeting all visiting entomologists were the guests of state entomologist Worsham and his assistants at a smoker which was held at the University Club. There was a large attendance and all those present united in extending their thanks to the hosts of the occasion.

The program of scientific papers was introduced by the address of President Parrott on "The Growth and Organization of Applied Entomology in United States." This was followed by a series of papers on the organization of various kinds of special entomological work which is being carried on in different sections of the country. On Thursday morning a number of papers were presented bearing on spraying with poisonous and contact insecticides; on fumigation and life history studies on a number of orchard and garden pests. At the afternoon session, papers were read on experimental work on a number of insects which are destructive to garden and field crops and forests, and several papers on insect parasitism were also presented.

At the closing session on Friday morning, January 2, a paper was presented by Dr. L. O. Howard on "The Education of the Entomologist in the Service of the United States Department of Agriculture," and this was followed by a number of interesting papers on mosquitoes and house flies, which took up observations on their habits and experiments bearing on their control.

All the papers presented at the meeting will be published in full in the *Journal of Economic Entomology*.

A. F. BURGESS,
Secretary

THE AMERICAN PHILOSOPHICAL ASSOCIATION

THE association at its annual meeting at New Haven, Conn., in December, elected the following officers:

President—Professor J. H. Tufts, of Chicago University.

Vice-president—Professor W. H. Sheldon, of Dartmouth College.

Secretary-treasurer—Professor E. G. Spaulding, of Princeton University.

New Members of the Executive Committee—Professors W. T. Bush, of Columbia University; I. W. Riley, of Vassar College, and C. M. Bakewell, of Yale University.

The program was of exceptional interest this year, in that two days' sessions were devoted to the discussion of one subject, "The Problem of Values in its Various Aspects." Miscellaneous papers were read on this subject at the first day's sessions, and the entire second day was devoted to discussion. The leaders in this debate were Professor R. B. Perry, of Harvard University, and Professor W. H. Sheldon, of Dartmouth College. The association, on the whole, found this procedure more profitable than the usual short discussions of many miscellaneous papers. A joint discussion was also held with the American Psychological Association on "The Standpoint and Method of Psychology." Leaders in this discussion were Professor John Dewey, Professor F. M. Urban, Professor J. E. Creighton and Professor Hugo Münsterberg. The two associations participated in a joint dinner on December 30 at the Hotel Taft, and Professor Howard C. Warren, of Princeton University, president of the Psychological Association, read on this occasion an extremely interesting address on "The Physical and the Mental."

President McGilvary, of Wisconsin, addressed the two associations on December 29 on "Time and the Experience of Time."

E. G. SPAULDING,
Secretary

THE SOUTHERN SOCIETY FOR PHILOSOPHY AND PSYCHOLOGY

THE society held its ninth annual meeting at Atlanta, Ga., Wednesday, December 31, 1913, and Thursday, January 1, 1914, in affiliation with the American Association for the Advancement of Science. Fifteen of the fifty-six members were present. Three sessions were held, one on Wednesday forenoon in conjunction with Section H of the American Association for the Advancement of Science, one on Thursday forenoon, and one on Thursday afternoon in conjunction with Sections H and L. The meetings were held in the chemical lecture room of the Georgia School of Technology. On Wednesday evening the members of the society and of Sections H and L were entertained at a smoker at the University Club by Dr. H. J. Pearce, the president of the society. The president's address, entitled "The Limitations of

Knowledge," was given at 4:30 on Thursday afternoon.

The following items were passed upon at the business meeting held Thursday forenoon:

1. The place of holding the next meeting was left to the council for decision. Professor Ogden invited the society to come to Knoxville, but as the American Association for the Advancement of Science will meet at Philadelphia the suggestion was made that the society meet one day at Washington and then join some of the sections at Philadelphia.

2. The following officers were elected:

President—J. B. Watson, Johns Hopkins University.

Vice-president—Josiah Morse, University of South Carolina.

Secretary-treasurer—W. C. Ruediger (re-elected), The George Washington University.

Council for three years—E. F. Buchner (re-elected), Johns Hopkins University, and L. R. Geissler, University of Georgia; for two years J. C. Barnes, Maryville College; for one year W. H. Chase, University of North Carolina.

3. The following new members were elected: Dr. Edwina Abbott, Tulane University; Mrs. A. H. Arlitt, Tulane University; Dr. F. M. Barnes, St. Louis; David June Carver, Johns Hopkins University; Edward Conradi, Florida State College for Women; Dr. Harvey W. Cox, University of Florida; Professor Ezra B. Crooks, Randolph-Macon Woman's College; Miss Lucile Dooley, Knoxville, Tenn.; James Wallace Hopkins, Tulane University; Miss Marguerite Kehr, Knoxville, Tenn.; Professor Mark Edgar Sentelle, Davidson College; Dr. E. K. Strong, Jr., Columbia University.

4. The accounts of the treasurer, which were audited for the council by Professor Ogden and approved by the society, showed a balance on hand, December 31, 1913, of \$82.44. Of this \$15 was allowed the secretary toward defraying his expenses incident to the Atlanta meeting.

5. The secretary was authorized to frame an amendment to Section 1, Article III., of the constitution changing the term of office for the secretary-treasurer from one year to three years.

The following papers were read by members of the society either before sessions of the society alone or before joint sessions with Sections H and L.

"New Interpretations of Psychoanalytic Data," by Tom A. Williams.

"Correlation of Physical and Mental Measurements," by J. C. Barnes.

"Dreams as Retrostructive Interpretations," by W. B. Smith.

"The Master Motive in a Theory of Knowledge," by John G. Harrison.

"Rational Psychotherapy," by Robert S. Carroll.

"Concluding from Negatives," by W. B. Smith.

"Concerning the Psychological Origin of Creation Stories," by W. T. Shepherd. (By title.)

"A Test for Adolescents," by Eleanor D. Keller.

"Avocational Education," by W. C. Ruediger.

"The Correlation of Abilities in High School Girls," by E. F. Buchner.

"Experiments with Free Association Method," by R. M. Ogden.

W. C. RUEDIGER,
Secretary

SOCIETIES AND ACADEMIES

THE ANTHROPOLOGICAL SOCIETY OF WASHINGTON

A SPECIAL meeting of the Anthropological Society of Washington was held at 4:30 P.M., December 9, 1913, in Room 43 of the new museum building, the president, Mr. Stetson in the chair. About fifty persons were present.

Dr. Charles B. Davenport, of the Carnegie Institution, director of the laboratory at Cold Spring Harbor, Long Island, addressed the society on "Man from the Standpoint of Modern Genetics." He said that the problem of the origin of species has now become largely reduced to the problem of the origin and survival of the characters of the species. Since groups differentiated by a single hereditary character are called biotypes, the question of the origin of species is now that of the origin of biotypes. Man is a congeries of biotypes. If these do not exist as distinct elementary species it is because of the tremendous hybridization that is taking place between biotypes. These biotypes are most nearly realized in islands, peninsulas and out-of-the-way places. The most distinct of the human races exist to-day in such places as Australia and Ceylon, the Japan Islands (Ainos), Cape Horn and inside of the Arctic circle within the old and new world. But in small islands of the coast, where people have been long settled and little disturbed, they tend to approach a pure race or biotype.

Under the shelter of this isolation, incidentally, opportunity has been afforded for an adjusted race to spring up; but there is danger of deterioration through too close interbreeding. Hybridization, as stated, is constantly preventing the com-

plete development of these biotypes. This hybridization has gone on with man since early times so that few biotypes are now actually realized. It is now going on faster than ever and even the rare fairly pure biotypes are fast disappearing from the globe. The work of the anthropologist of the future must be largely with these hybridized biotypes; his principal study will be the inheritance of the various differential traits.

The method of inheritance of some of these traits has already been studied. Thus we know that the brown iris is dominant over its absence, as seen in blue eyes. The skin color of the negro is complex, being due to two double (or four) factors; and these may work independently of one another, so that we have one, two, three or four pigment factors in the skin, producing the typical quadroon, mulatto, Sambo and full negro skin coloration. Dark brown hair is dominant over blond hair; so that when both parents have only blond hair the children are all blonds. Two red-haired parents have only red-haired offspring. But two glossy black-haired parents may carry red hidden and so have red-haired children, as we so often see among the Irish. Kinky or curly hair is dominant over straight. Two straight-haired parents have, typically, only straight-haired children.

Many "hereditary diseases" depend on a "diathesis," a non-resistance that is clearly inherited and if matings of like or of relations occur extensively, we have the elements necessary for the production of a biotype. Among such diseases are Huntington's chorea, presenile cataract and night blindness. Other diseases are inherited as sex-linked characters—such are color blindness and the "bleeding" tendency. Very striking is the tendency to produce a real biotype of the imbecile class, because imbeciles tend to segregate themselves and to intermarry. This is the reason why we get such histories as the Nams of New York, the Hill Folk of Massachusetts, the Pineys of New Jersey and the Jukes of New York. Any condition that favors consanguineous matings, or matings of likes, favors the formation of a variety of the human race, as Dr. Alexander Graham Bell (the Francis Galton of America) long ago pointed out. Thus most institutions which do not provide permanent custodial care tend to promote such marriages; for example, among the deaf-mutes, tubercular, nervous, paupers and even alcoholics and users of narcotics. On the other hand, in consequence of social stratification fine near-biotypes, like the Lovells of Boston, the

Dwight-Woolseys of Connecticut, the Bayard-Jay-Livingston Complex of New York, and the first families of Virginia have arisen. Actors tend to marry each other and so rapidly produce nearly pure strains of histrionic talent. This nation owes more than it recognizes to its strains of inventors, surgeons, commanders, statesmen, authors, artists and financiers that have made her famous and given her the high standing she has attained in the family of nations.

Thus biotypes in man prove to be real things and their study is quite as much within the proper field of research of the anthropologist as are the commonly recognized races of men.

The paper was discussed by Dr. Hrdlička.

DANIEL FOLKMAR,
Secretary

THE ENTOMOLOGICAL SOCIETY OF WASHINGTON

At the 223d regular meeting of the society, held January 7, Mr. August Busck gave his retiring presidential address entitled, "Notes on the Classification of the Microlepidoptera." In this address Mr. Busck reviewed the characters which have been used in classifying the Microlepidoptera, telling how the venation is now used most extensively and emphasizing this as the most important character in judging the phylogenetic relationships of superfamilies, families and genera. He presented his views on the phylogeny of the Microlepidoptera arranged graphically in a phylogenetic tree. This address, as well as some of the discussion which it called forth, will be published in an early number of the *Proceedings of the Entomological Society of Washington*.

The meeting was very well attended by members and visitors. The most distinguished visitor was the Canadian entomologist, Dr. C. Gordon Hewitt.

THE PHILOSOPHICAL SOCIETY, UNIVERSITY OF VIRGINIA, MATHEMATICAL AND SCIENTIFIC SECTION

THE fourth meeting of the year 1913-14 was held January 20, 1914.

Professor T. L. Watson and Mr. J. H. Cline presented a paper entitled "Some Examples of the Intercession Type of Stream Piracy in Western Virginia."

Professor W. A. Kepner and Mr. W. H. Taliaferro presented a paper entitled "The Organs of Special Sense of *Prothyncus*."

L. G. HOXTON,
Secretary

THE SCIENCE CLUB OF THE UNIVERSITY OF WISCONSIN

DR. FREDERIC E. WRIGHT, petrologist of the Geophysical Laboratory of the Carnegie Institution of Washington, gave an account of "Some Phases of the Work of the Geophysical Laboratory" before the Science Club of the University of Wisconsin at its 127th meeting on December 10, 1913.

The scope of the Geophysical Laboratory of Washington is restricted to the field of experimental geology, and particularly to the quantitative investigation of the chemical, physical and physico-chemical phenomena of minerals. Artificial minerals are prepared from pure substances under known conditions, and are studied and compared with natural minerals. A great deal of preliminary work has been done by the laboratory in devising, making and standardizing apparatus.

Dr. Wright described and illustrated with color photographs projected on the screen the laboratory, its equipment and methods of work; performed experiments showing phenomena of crystallization, eutectic fusion, recalcrescence and other inversion phenomena; and showed by means of projected color photographs the polarization, and other, phenomena employed in the microscopic analysis of minerals. Dr. Wright exhibited a model of a fusion-equilibrium surface in trilinear coordinates representing the properties of all possible mixtures of lime, magnesia and silica, the result of six years' research in the laboratory. He also gave an account of the work of Dr. Day and Dr. Shepherd, in collecting and examining volcanic gases, and projected on the screen color photographs taken during the descent into the crater of Kilauea, showing in the most vivid way the phenomena of an active volcano at close range. The work of the expeditions to Kilauea has shown that water is present in the magma of volcanoes, at least of Kilauea; that this water is not of atmospheric origin, since no argon accompanies it; and that the heat of recombination of the dissociated gases is sufficient to keep the lava molten.

In response to a question by Dr. C. K. Leith, Dr. Wright gave a brief account of the present state of his research on the internal forces of crystals by determining the changes of form and other properties of crystals in response to change of temperature and pressure.

ERIC R. MILLER,
Secretary

Polygon Cameras

"THE CAMERA OF QUALITY"

with

Rietzschel Double Anastigmats

are the embodiment of all that is desirable in cameras. They are compact, small, and light in weight, yet they are very reasonable in price: "They fit the Pocket." They are made from **miniature** size up to 5x7 inches, in all styles. All are built of light but indestructible metal; all are leather covered; all have leather bellows; all have rising, falling and cross front; all have detachable lensboard; all have quickly reversible ground glass; all are fitted with double anastigmats, the better ones with the finest cemented lenses ever put on the market, in compound shutter.

We also sell

ERNEMANN Cameras,
Double Anastigmats and
Motion Picture Apparatus

MEYER CAMERA & INSTRUMENT CO., Inc.

St. Louis, Mo.

**Theresa Seessel Research Fellowships to
promote original Research in
biological studies**

YALE UNIVERSITY

Two fellowships yielding an income of \$1,000 each. Preference is given to candidates who have already obtained their Doctorate and have demonstrated by their work fitness to carry on successfully original research work of a high order. Applications should be made to the Dean of the Graduate School, New Haven, Conn., before April 1st; they should be accompanied by reprints of scientific publications and letters of recommendation.

MARINE BIOLOGICAL LABORATORY WOODS HOLE, MASS.

1. Zoology. Preserved material of all types of animals for class work and for the museum.
2. Embryology. Stages of some invertebrates, fishes (including Acanthias, Amia and Lepidosteus), Amphibia, and some mammals.
3. Botany. Preserved material of Algae, Fungi, Liverworts, and Mosses. Price lists furnished on application to GEORGE M. GRAY, Curator, Woods Hole, Mass.

ELEVENTH EDITION
THE MICROSCOPE,
an introduction to Microscopic Methods and to Histology, by
SIMON HENRY GAGE of Cornell University. The 11th edition
has eight pages of new matter and corrections, otherwise it is
like the 10th ed. Price \$2.00 postpaid.

BLAKISTON

DISEASES OF OLD AGE AND THEIR TREATMENT

Including Physiological Old Age, Home and Institutional Care

By I. L. NASCHER, M.D.

NEW YORK

With an introduction by A. JACOBI, M.D. 50 plates containing 81 illustrations.

Octavo. viii+515 pages. Cloth, \$5.00 Postpaid.

The author of this work has devoted much time to the study of senile diseases and their treatment. His vast experience in this particular field has led to the discovery of many important facts that are of practical value in science and medicine. In recent years considerable work has been done in blood-pressure investigations, cancer, research, arteriosclerosis and other factors which are related to senility and its diseases, and the extent and depth, and ever-increasing scope of these investigations, which are really studies into the causes and results of senile changes, give promise of ultimate success in discovering the fundamental causes of senescence.

As this book is a pioneer in the field, one may expect to find in it much that is new and of general interest. In his preface the author states, "there is another point of view from which the physician should consider the aged and their diseases, that of the scientist, for here is a most interesting study, presenting problems that are intimately bound up in the grand mystery of life and death."

IMPORTANT BOOKS IN SCIENCE

THE MECHANISTIC CONCEPTION OF LIFE. Biological Essays by JACQUES LOEB, Member of the Rockefeller Institute for Medical Research. 238 pages, 12mo, cloth, postpaid, \$1.65.

In this book Professor Loeb presents many of the current problems in biology, and discusses the question whether the phenomena of life can be explained by physical and chemical laws. He finds it possible to control by physical and chemical means not merely the processes of reproduction, but also the conduct of animals with reference to environment.

JOHNS HOPKINS HOSPITAL BULLETIN. All eager to know more of the origin of life will find no modern book of its size nearly so instructive or inspiring.

HEREDITY AND EUGENICS. By JOHN M. COULTER, WILLIAM E. CASTLE, EDWARD M. EAST, WILLIAM L. TOWER, and CHARLES B. DAVENPORT. 312 pages, 8vo, cloth: postpaid, \$2.70.

Leading investigators have in this work made clear the present position of evolution, experimental results in heredity in connection with both plants and animals, the enormous value of the practical application of these laws in breeding, and human eugenics. The volume is profusely illustrated.

BRITISH MEDICAL JOURNAL. Those who are desirous of arriving at an estimate of the present state of knowledge in all that concerns the science of genetics, the nature of the experimental work now being done in its various departments, . . . and the prospects, immediate or remote, of important practical application, cannot do better than study *Heredity and Eugenics*.

AMERICAN PERMIAN VERTEBRATES. By SAMUEL WENDELL WILLISTON, Professor of Paleontology in the University of Chicago. 152 pages, 39 plates, 8vo, cloth: postpaid, \$2.68.

This work comprises a series of monographic studies, with briefer notes and descriptions, of new or little-known amphibians and reptiles from the Permian deposits of Texas and New Mexico. The work is illustrated by the author. **ATHENAEUM.** The paleontologist will welcome the work as a solid contribution to our knowledge of a fauna which is of exceptional interest to the student of evolution, inasmuch as it includes forms that help to bridge over some of the differences between reptile and amphibians.

MORPHOLOGY OF GYMNOSPERMES. By JOHN M. COULTER, Professor of Botany, and CHARLES J. CHAMBERLAIN, Associate Professor of Botany, University of Chicago. 470 pages, 462 illustrations, 8vo, cloth: postpaid, \$4.22.

Each of the seven great groups of gymnosperms is here presented in detail, and a final chapter discusses the problem of phylogeny and points out the evolutionary tendencies. The extinct groups are now included for the first time and vascular anatomy is recognized as a morphological subject of first importance. The illustrations are numerous and in large part original.

NATURE. The book is an invaluable record, admirably illustrated, of our present knowledge of the older type of seed-plants.

Recent Publications of the New York Botanical Garden

Journal, Vol. XIV, No. 168. An illustrated monthly containing notes and non-technical articles of general interest. \$1.00 a year.

Mycologia, Vol. VI, No. 1. An illustrated bimonthly publication devoted to fungi and lichens. \$3.00 a year. This number contains: Illustrations of Fungi—XVII, by William A. Murrill; A Preliminary Study of the Genus *Lamprospora*, by Fred J. Seaver; Notes on *Uredinopsis mirabilis* and Other Rusts, by W. P. Fraser; Observations on the Use of Ridgway's New Color-Book. The Color of the Spores of *Volvaria speciosa* Fr., by L. C. C. Krieger; New or Interesting Fungi, by David Ross Sumstine; Aerial Galls of the Mesquite, by F. D. Herald; News and Notes; Index to American Mycological Literature.

Bulletin, Vol. VIII, No. 29. \$3.00 per volume. This number contains the annual report of the Director-in-Chief and other official documents.

Memoirs, Vol. 3. \$2.00. Studies of Cretaceous Coniferous Remains from Kreischerville, New York, by Arth. Hollick and Edward C. Jeffrey, vii+138 pp., with 29 plates.

Vol. 4. \$2.00. Effects of the Rays of Radium on Plants, by C. Stuart Gager, vii+278 pp., with 73 figures and 14 plates.

North American Flora. Descriptions of the wild plants of North America. To be complete in about thirty volumes of four or more parts each. Subscription price for entire work \$1.50 per part; separate parts \$2.00. Twenty parts have been issued, seven on fungi, ten on flowering plants, one on ferns, and two on mosses. Parts recently issued are:

Vol. 15, part 1, issued June 14, 1913. Sphagnaceae, Andreaeaceae, Archidiaceae, Bruchiaceae, Ditrichaceae, Bryoxiphiaceae, and Seligeriaceae.

Vol. 15, part 2, issued August 8, 1913. Dicanthaceae and Leucobryaceae.

Vol. 22, part 5, issued December 23, 1913. Rosaceae (pars).

Contributions. A series of technical papers by students or members of the staff. \$5.00 per volume; 25 cents each. Recent numbers: 159. A Case of Bud-Variation in *Pelargonium*, by A. B. Stout. 160. Studies on the Rocky Mountain Flora—XXIX, by Per Axel Rydberg. 161. West Indian Mosses—I, by Elizabeth G. Britton. 162. Phytogeographical notes on the Rocky Mountain Region I, Alpine Region, by P. A. Rydberg.

It is a source of satisfaction to record that the experience of the past year supplements that of a year ago in showing a general improvement in the relations which the institution sustains to other organizations and to the world of learning at large. The obviously rational tendency to take an objective view of the institution and its work and to measure them by the more permanent standards available is now everywhere distinctly visible. This tendency is manifested in many ways: by an increasing demand for exact information concerning the plan, scope and development of the institution as a whole; by an increasing critical interest in the investigations, the equipments and the programs of work of our departments of research; and by an increasing demand for precise knowledge concerning special apparatus and special technique developed by our departmental staffs. In addition to these numerous demands for correct information with respect to ways, means, methods and results, there are now presented also, not infrequently, requests for investigations in cooperative enterprises for which other organizations, or in some cases individuals, are willing to supply the necessary funds. This is a manifestation which, while not unanticipated, has developed somewhat earlier than expected. It calls for considerable attention, since it is likely to grow with time in proportion as the institution demonstrates capacity for trustworthy

MSS. intended for publication and books, etc., intended for review should be sent to Professor J. McKeen Cattell, Garrison-on-Hudson, N. Y.

¹ From the report of the president for the year ending October 31, 1913.

management of funds and for effective conduct of research.

On the death of Dr. Fletcher, November 8, 1912, editorial supervision of the *Index Medicus* was placed in charge of Dr. Fielding H. Garrison, who had long been associated as principal assistant with Dr. Fletcher in the publication of this work. Continuity of plan and purpose is thus assured in the perpetuation of this current bibliography, while the responsible editorship falls to one whose qualifications for the task have met the exacting standards of his eminent predecessors.

In accordance with the authorization voted by the Board of Trustees at its meeting of December 13, 1912, a department of human embryology, under the direction of Professor Franklin P. Mall, with a small staff of associates and collaborators, has been planned and is already engaged in active research. In arranging for this department the institution is peculiarly fortunate not only in enlisting the directorship of Professor Mall, but in starting from a foundation furnished by his remarkable collection of human embryos. It will be seen also that this enterprise is of far greater import than might at first appear, for it has fundamental relations to the science of anthropology as well as to those of anatomy, physiology and pathology, which latter, indeed, from some points of view, may not improperly be regarded as branches of the former widely inclusive science. The efforts of the institution to enter the domain of anthropology, to which reference is again made in a later section of this report, are thus in part realized in a most effective way.

Another noteworthy event of the year is the construction of two new buildings, a heating and lighting plant, and an additional laboratory, for the department of experimental evolution, authorized by the

board of trustees at their last meeting. Plans in illustration of these buildings, which are now nearing completion, will be found in connection with the annual report of the department in the current year book. Two of the many uses which this laboratory is designed to serve in the immediate future are those of housing and further experimentation upon the unique collection of pedigreed pigeons, studied for many years by the late Professor C. O. Whitman, whose researches the institution has undertaken to complete and to publish. In accordance with the agreement entered into with Professor Whitman's heirs this unrivaled collection of biological material will become the property of the institution, and arrangements have been made for its transfer to Cold Spring Harbor from Chicago before the end of the calendar year.

Similarly, two items from the current history of the department of terrestrial magnetism are worthy of mention here. One of these is the approaching completion of an office and laboratory building whose construction was approved by the board of trustees a year ago. Floor plans of this building are incorporated in the annual report of the director of the department in the current year book. The building is situated on a very favorable, elevated site of a little less than seven acres in the District of Columbia, near Chevy Chase, and near the western boundary of Rock Creek Park. It will be fire-proof, will furnish safe storage for the extensive records already acquired by the department, and will afford opportunity for experimental researches in terrestrial magnetism which may be confidently expected to give deeper insight into this obscure but at present highly utilitarian property of our planet. The other noteworthy event referred to is the near com-

pletion of a circumnavigation voyage of about three and a half years' duration and of courses aggregating upwards of 80,000 miles, by the non-magnetic ship *Carnegie*. Experience with this ship shows that a magnetic survey of the oceans is a somewhat less formidable undertaking than a magnetic survey of the continents, for the latter are still, on the whole, less accessible than the former since the advent of this non-magnetic nautical observatory. Great credit is due to Mr. W. J. Peters, commander of this ship, for assiduous attention not only to her safety, but also to the effectiveness of her mission in the immediate interests of the world's navigation and in the more important, though less obvious, interests of terrestrial physics.

Reference was made in the report of a year ago to the construction of a fireproof office building at Pasadena, California, for the staff of the solar observatory. This building has been occupied during the past year, and its characteristics are shown by illustrations in photo-perspective and in plan in the current year book. In addition to supplying adequate quarters for the departmental staff and safe storage for the extensive records of the observatory, it furnishes in its sub-basement a constant-temperature room in which will be installed a dividing engine designed especially to rule diffraction gratings for use with the other optical apparatus of the observatory. Such an engine has been constructed at the shops of the observatory during the past year by Mr. Jacomini, mechanician of the departmental staff, in collaboration with Dr. John A. Anderson, of Johns Hopkins University, who has supplied tests of precision which have led to a degree of perfection not hitherto attained in this excessively difficult and delicate kind of construction. It is gratifying to report also in this connection that the glass disk

for the 100-inch telescope, which a year ago had developed distortions indicating defective stability, is now meeting all essential requirements and giving promise of an optical surface equal to, if not superior to, that of the 60-inch mirror. Accordingly, work of construction for the foundation and for the mounting of this 100-inch telescope is now proceeding as rapidly as the conditions of safety and of efficiency in such a novel undertaking will permit.

OUTLINE OF RESEARCHES OF THE YEAR

As is abundantly indicated in previous reports, and as is evident to any deliberate reader of the bewildering miscellanies presented in the year books, the diversity and the complexity of the investigations going forward under the auspices of the institution preclude anything like a clear and complete summary of their scope, progress and prospective value within the limits of an administrative report. The general reader must take it for granted (provisionally at least) that these investigations are in the main worth undertaking and thus await the verdict of time through the aid of a growing critical public opinion; for in proportion as such investigations are fundamental, and hence worth carrying on, they will be difficult of exposition and more difficult of comprehension. Concerning this matter there appears to be prevalent a popular fallacy to the effect that writers untrammelled by competent scholarship, but who possess verbal facility, are better qualified to expound a technical subject than those who have developed it or contributed thereto; and along with this fallacy there is frequently coupled another to the effect that ours is an age of narrowing specialization, whose evil effects may be remedied by resort to literary views of phenomena and by re-

stricting the range of increasing knowledge. While patiently tolerant with these extremes of opinion, it is obviously inadmissible to adopt either of them here. We may neither pretend to exposition of knowledge not acquired nor deprecate the excess of knowledge possessed by experts in this or that field of science. It is hoped, therefore, that the brief summaries given in the president's reports may not be mistaken for adequate accounts of current progress or for sufficient recognition of the merits of the researches referred to.

DEPARTMENTS OF RESEARCH

In accordance with the views just set forth it seems appropriate at this time to limit still more narrowly than hitherto the brief summaries of departmental work and to invite attention still more directly to the departmental reports published in the year book. All of the departments of research of the institution hitherto reported upon are now well-defined organizations, each of them independent of and more or less isolated from the others, and each of them devoted to a field which, while in some cases related to, does not encroach upon the fields of others. Each of them possesses thus a degree of autonomy which calls for a corresponding degree of freedom in the rendition of annual reports and accounts of progress. But along with this autonomy, indispensable to the highest efficiency in such organizations, it is equally essential that there should coexist a fraternity of interest and a solidarity of purpose centering in the institution as a whole. First steps toward development of these latter desiderata were taken in December, 1909, on the occasion of the annual meeting of the board of trustees, when the administration building was dedicated and when the directors of departments of research were invited to give exhibits of the salient features of their work up to that

time. On the same occasion two related experiments were inaugurated, namely, that of a lecture to the trustees and their guests from the head of a department of research, and that of a conference between the directors of departments and the president. The results of these experiments have been so favorable that the plan of having an annual lecture, an annual conference, and exhibits of departmental work at intervals of three to five years, has come to be adopted by common consent. In addition to the exhibit held in December, 1909, another was held in December, 1911, on the occasion of the tenth anniversary of the foundation of the institution.

By reason of the decision of the board of trustees a year ago to take part in the Panama-Pacific Exposition, to begin in San Francisco in February, 1915, it is proposed to hold the next departmental exhibit in the administration building at the time of the meeting of the board of trustees in December, 1914. It will thus be practicable to bring together an aggregate from which (by aid of counsel from departmental representatives) a more restricted exhibit may be drawn for the Panama-Pacific Exposition. On account of this circumstance and on account of the fact that the departments on the average, as well as the present administration, will have completed a first decade in the institution's history a year hence, it seems desirable to reserve any more elaborate summaries of work accomplished and now under way, whether of departments or of research associates, until that time. Accordingly this section of the present report is limited to something less than the usual extent.

DEPARTMENT OF BOTANICAL RESEARCH

Studies of the Salton Sea,² carried on

² Often by earlier writers called Cahuilla Basin, more frequently called Salton Sink, and now

during the past seven years by this department in collaboration with a number of contributing specialists, have been brought together during the year in a volume now in press under the title "The Salton Sea: A Study of the Geography, the Geology, the Floristics and the Ecology of a Desert Basin," as publication No. 193. A great number of interesting questions in geography, geology, botany, chemistry, microbiology, plant physiology, climatology, etc., are discussed in this volume. Of these, an instructive abstract is given by the director in his current report.

Among many researches carried on by the director, mention may be made of his cultivation of second and third generations of mutants arising from ovarial treatments of plants and resulting in further noteworthy morphological and physiological departures from the original parent stocks. Of members of the departmental staff, Dr. Cannon has extended his fruitful studies of root systems of desert plants to include the corresponding characteristics of trees in the coastal climate of California and to the problem of treelessness in prairie regions. Dr. Forrest Shreve has given special attention to the factors involved in the transpiration of rain-forest plants and to the effects of mountain slopes and climatic conditions varying with altitudes and with exposures. Dr. Spoehr has continued his investigations of the action of light and heat in producing chemical changes in plant organisms, giving promise thus of important advances in the newer field of phytochemistry and photolysis.

Several collaborators have contributed to the varied work of the department during the year. Sections of the director's

called Blake Sea, in honor of Professor Blake, who, as geologist of the Williamson survey of 1853, first accurately interpreted this remarkable depression below sea-level.

report are thus devoted to accounts of the further experiments of Professor W. L. Tower on the evolution of chrysomelid beetles, for which facilities are provided at the Desert Laboratory; to the physical studies of Professor B. E. Livingston, formerly a member of the departmental staff, on the water relations of plants; to the determinations of autonomic movements in opuntias by Mrs. Shreve, whose volume on "The Daily March of Transpiration in a Desert Perennial" is in press as publication No. 194; to the investigation of Professor H. M. Richards on the acidity, the gaseous interchange and the respiration of cacti; to the surprising properties of the opuntias in fruit development, brought to light by Professor D. S. Johnson; and to the favorably progressing enterprise undertaken by the department, in collaboration with Dr. N. L. Britton and Dr. J. N. Rose, for a systematic determination of the distribution and relationships of the cactus family of plants.

DEPARTMENT OF EXPERIMENTAL EVOLUTION

The work of the year in this department records, among many other advances, additional contributions to the laws of human inheritance; the results of further and more conclusive studies of the transmission of traits in plants of the genera *Bursa* and *Enothera*; and some preliminary indications of specially instructive investigations in the field of biochemistry. The director has divided his time between researches based on breeding experiments carried on at his station and studies of data bearing on human heredity collected under the auspices of the Eugenics Record Office, of which he is also the directing head. In addition to the researches carried on by Doctors Banta, Gortner, Harris and Shull of the resident staff, Dr. A. F. Blakeslee, Dr. G. C. Bassett and Professor John H.

Gerould have pursued investigations in collaboration with this staff. One of the most important of these cooperative enterprises is the joint investigation of Dr. Blakeslee and Dr. Gortner on the low organisms called mucors, from which it appears that sex-differentiation in these organisms has a determinate physical basis. This conclusion appears to bear a close relation to similar fundamental conclusions reached independently in other lines of work by our research associates, Dr. Reichert and Dr. Osborne.

The exigencies of his experimental work going forward at the departmental station have prevented Dr. Shull from completing the manuscript of his account of the work of Luther Burbank. It has been arranged, therefore, that he shall spend some months abroad, beginning with October, 1913, in order that uninterrupted attention to this manuscript may enable him to finish it without undue delay. The importance of the biochemical laboratory, in charge of Dr. Gortner in connection with the department, has been well attested during the year by the aid he has rendered in the complex studies evidently essential to further advances in the problems of plant and animal evolution. The more adequate provision for this laboratory adjunct furnished by the new departmental buildings, already referred to, will make it practicable to utilize still more advantageously the highly developed qualitative and quantitative methods and data of the older science of chemistry.

DEPARTMENT OF ECONOMICS AND SOCIOLOGY

Substantial progress toward completion of the several contributions from the twelve divisions of this department to their projected basis for a social and economic history of the United States is reported by Professor Henry W. Farnam, chairman of

the department. It is estimated by him that six of the divisions will be able to present final reports within the next fiscal year. These are the divisions of population and immigration, in charge of Professor Willcox; mining, in charge of Mr. Parker; transportation, in charge of Professor Meyer; domestic and foreign commerce, in charge of Professor Johnson; labor movement, in charge of Professor Commons, and social legislation, in charge of the chairman. Delays due to the requirements of their primary occupations, to ill health or misfortune in the case of some collaborators, and to demands of public service in other cases, have prevented the remaining divisions from bringing their work to a similarly forward state.

The chairman again calls attention in his report to the desirability of reorganizing this department and placing it on a basis similar to that of all other departments of research of the institution. As to the appropriateness of this recommendation, there now appears to be no dissent, either within or outside the department. It is hoped, therefore, that such a reorganization may be consummated as soon as the work now in hand may be completed in accord with the original plan, if it should not appear advantageous to make the obviously desirable change at an earlier date. There is no doubt that the field of opportunity for effective pioneer work by such a department is in great need of present-day cultivation and that it extends indefinitely into the future.

THE GEOPHYSICAL LABORATORY

The preliminary stages in the development of this hitherto unique establishment may now be said to have passed, since laboratories similarly equipped and for like purposes are now being set up under other auspices. That the merits of the methods,

the apparatus and the earlier published researches of the geophysical laboratory should have been thus early recognized is at once a source of gratification to the institution and an additional stimulus to fundamental work in the difficult but ever fruitful domain of geophysics. In his annual report the director gives instructive accounts of the effects of pressure in the formation of minerals, of progress in the perfection of adequate appliances for calorimetric measures of minerals, of the factor of temperature in optical studies of crystals, of the results thus far obtained in volcano studies, and of the important economic investigations (now under way at the laboratory) of the secondary enrichment of copper sulphide ores. It had been hoped that the signal success attending the studies of Kilauea a year ago might be followed up during the past year, but in this the staff has met disappointment, for the volcano has been inactive and gives no warning of renewed opportunities.

The activities and productivities of the laboratory staff are indicated impressively by the 52 papers issued during the year, or now in press, reviewed in the report of the director. These have been, or will be, published in current journals. Several of them appear as duplicates by reason of translations into the French or the German languages; of these, it is interesting to note that a translation into French by Professor P. Chappuis has been made (for the *Journal de Physique*) of the work of Day and Sosman on "High Temperature Gas Thermometry," publication No. 157 of the Institution.

DEPARTMENT OF HISTORICAL RESEARCH

The purposes to which this department is devoted and the programs it proposes to follow have been outlined in the director's annual reports of the past seven years. He

took occasion also, in December a year ago, when he gave the annual trustees' lecture, entitled "The Future Uses of History," to present a fuller statement of these purposes and programs, as well as to indicate the rôle which history may fittingly play in the evolution of the social organizations which must occupy the attention of our successors. This instructive lecture was rendered available to a wider circle of interested students of history by publication in *The History Teachers' Magazine* for February, 1913.

Briefly stated, the main purposes of the department are two: first, to furnish aids, guides and reports which may give appropriate direction to the writers of monographs and general histories; and, secondly, to furnish full textual publication of important historical documents. Under the first of these heads the director reports very favorable progress toward completion of a series of three guides to the materials for American history in London archives and in the libraries of Oxford and Cambridge universities. The first volume of this series was issued as No. 90 of the institution's publications in 1908, and the other two volumes, now nearly through the press, are designated 90A and 90B, respectively. As to this series the director remarks in effect in his report that no similar inventory of like extent, concerning archive materials which London possesses for the history of any other nation, has ever been issued. Two additional volumes in this first division of activities have appeared during the year, namely, publication No. 163, "Guide to Materials for United States History in Mexican Archives," by Herbert E. Bolton; and publication No. 172, "Guide to Materials for United States History in Canadian Archives," by David W. Parker. Under this head also progress is reported in the work of Mr. Leland on

materials for American history in Paris archives, in the work of Professor Hill in Spanish archives, and in the corresponding work of Professor Faust in Switzerland and in Austria. Under the head of textual documents the director refers in some detail to progress in the preparation of the projected collections of "Letters of Delegates to the Continental Congress," of "European Treaties Bearing on United States History," of "Proceedings and Debates of Parliament Respecting North America, 1585 to 1783," and to a preliminary report on papers of the Royal African Company in the Public Records Office of London.

Attention is especially invited to the director's interesting review of the work of the department during the first decade of its existence, completed with this fiscal year. Some idea of the extent of this work may be gained from the list of departmental publications cited, the number of these being 17, with an aggregate of over 5,000 pages; while the bulky correspondence of the institution as a whole is in some degree indicated by the fact that this department records an aggregate of upwards of 20,000 letters in its decennial inventory.

DEPARTMENT OF MARINE BIOLOGY

When the laboratory of this department was established on Loggerhead Key, Dry Tortugas, Florida, now nearly ten years ago, Fort Jefferson, on an adjacent island, was an important base station of the United States navy and transportation to and from points on the Gulf coast was a matter of daily occurrence. In the meantime, however, this station has steadily diminished in importance and is now virtually abandoned as a naval base. This change of conditions shifts the burden of transportation between the laboratory and the

nearest port, Key West, about thirty miles distant, wholly upon the department; and the resulting increased cost and inconvenience have led the director to recommend a gradual transfer of his laboratory and activities to a more favorable site. Preliminary investigations indicate that such a site may be had in Jamaica, where health conditions and transportation facilities have been much improved in recent years, where the cost of labor and subsistence is low, and where such an international scope as best benefits marine biology could be readily developed. It may be anticipated that definite plans for an advantageous change of site will be matured during the coming year and ready for submission to the board of trustees in December, 1914.

The department has suffered serious loss during the year in the untimely death of a remarkably able research associate, George Harold Drew. It has met with a reverse also in the temporary illness of another research associate, Dr. T. Wayland Vaughan. Drew and Vaughan had under way important investigations, originating at Tortugas, for the furtherance of which the departmental expedition of this year to Torres Straits was largely planned and authorized. Drew had made the discovery at Tortugas that the so-called coral mud in that vicinity is not due to corals, but has been precipitated through the chemical agency of a bacillus abundant in the surface waters of the tropical Atlantic. Vaughan, on the other hand, had made quantitative studies of the growths of coral organisms at Tortugas and of the closely correlated deposits or reefs. Jointly their investigations promised a solution of the long-vexed problem of the origin of such reefs and it was hoped that the expedition to Torres Straits and Great Barrier Reef would enable them to secure the additional data essential to final proof. In spite of

these adversities, however, the director and four associates sailed from San Francisco for Sidney, Australia, on July 23, 1913, and arrived at Torres Straits early in September. When last heard from, in September, the party was reported all well on Murray Island.

The laboratory season at Tortugas extended from April to June, inclusive, and twelve collaborators availed themselves of the facilities afforded for their researches. Summaries of these are given by the director in his current report, while more elaborate accounts are furnished by the investigators themselves in appendices to that report. Two additional volumes of contributions from the Tortugas laboratory are in press as publications Nos. 182 and 183.

DEPARTMENT OF MERIDIAN ASTROMETRY

On the death, October 5, 1912, of Professor Lewis Boss, director of this department since its establishment in 1906, his son, Mr. Benjamin Boss, long associated with his father in meridian astrometry, was made acting director. Adherence to the original program, so indispensable to the formidable enterprise this department has under way, is thus assured. The extensive computations essential in the derivation of the great number of stellar positions observed at the temporary observatory at San Luis, Argentina, are going forward at a favorable rate, so that the inclusive catalogue of precise positions for stars in both hemispheres may be expected in due time. Some instructive results of these computations, showing the stability of the San Luis meridian mark (*mire*), the diurnal variation of the clock corrections, and the changes of personal equation for day and night observations are given in the report of the acting director.

As in most lines of fruitful research, the

work of this department is noteworthy for its by-products, or for contributions it is making to allied lines of inquiry. Obviously, a first requisite to a knowledge of stellar motions lies in precise determinations of stellar positions at different epochs. The so-called proper motions of stars are thus brought to light, and from these it is possible to determine also the motion of our solar system. But now comes the surprising discovery that these proper motions, hitherto supposed to be of a random character, are of a systematic nature dependent in large degree, apparently, on the stage in evolution any individual star has reached and on the group to which it belongs. A new and peculiarly fascinating field is thus opened to astronomers of all kinds, and the by-products referred to seem destined to prove not less important than its primary object in positional astronomy. The world of astronomy, however, is anxiously awaiting the attainment of this object, as is well shown by the fact that the preliminary catalogue issued by the department three years ago is already out of print.

THE NUTRITION LABORATORY

One of the reasons which helped seven years ago to determine the location of this laboratory was found in the expectation that several hospitals would be erected in the near vicinity. This expectation has now been realized by the completion during the past year of the Peter Bent Brigham Hospital, the Collis P. Huntington Memorial Hospital, and of two hospitals for infants and children respectively. The environment and the opportunities for securing pathological subjects as well as clinical cooperation and counsel are therefore highly favorable for the researches undertaken by this establishment. That it has entered a fruitful field of activity is well attested by the wide interest shown in

its publications already issued, by the desires of experts at home and abroad to learn of the ways and means employed, and by the duplication in laboratories of other countries, as well as in those of America, of apparatus developed.

But science is cosmopolitan, and although many novel enterprises may be said to have originated with the institution, it may not lay claim to any monopoly in research; it can only contribute here and there in a limited degree to the ever-expanding aggregate of verifiable knowledge. In recognition of these limitations the director has appropriately adopted the plan of inspecting, at frequent intervals, the laboratories, the special apparatus and the technique developed elsewhere for the same and allied work. Thus he has made during the past year a third triennial tour of European laboratories, hospitals, etc., devoted to such work. This has afforded opportunity for numerous advantageous conferences with colleagues and for the selection of new apparatus of proved utility; while the director has been able during the same time to give counsel in respect to the adoption in other laboratories of apparatus and methods similar to those of the nutrition laboratory. The latter, therefore, like the geophysical laboratory, is no longer distinguished by its singularity, but must now enter upon a career of friendly rivalry with many cognate establishments.

For details of the investigations of the year, reference must be made to the director's report. They are summarized by him under thirteen principal heads, which range from studies of metabolism in infants, through those of normal metabolism in adults, up to studies of chronic starvation and diabetes mellitus. Many publications issued or in press during the year are also reviewed by the director in his report. Considerable new apparatus has been acquired

and earlier forms of equipment have undergone modifications suggested by experience. Interesting mention is made of visiting and cooperating investigators, of the special researches of the laboratory staff, and of the conferences had by the director during his trip abroad. The staff has been enlarged during the year by the addition of Professor Raymond Dodge, who will undertake work in the psychology of nutrition, and by Mr. E. H. Lange, who will serve as physicist for the staff.

DEPARTMENT OF TERRESTRIAL MAGNETISM

As already indicated in an earlier section of this report, one of the noteworthy events of the year for this department will be the completion of the second cruise of the non-magnetic ship *Carnegie*. She is now on the last stretch of this cruise and may be expected to arrive at a home port before the end of the calendar year, having been continually in service since June 20, 1910. The aggregate distance traversed in her two cruises will be in round numbers 80,000 miles. The corresponding distance covered by the chartered ship *Galilee*, in the Pacific Ocean during 1905-08, is 60,000 miles. Thus the total distance traversed up to date in the magnetic survey of the oceans is 140,000 miles, or about six times the circumference of the earth. Accurate magnetic data have been obtained thereby in all of the oceans between the parallels of 50° north and 50° south latitude, or near the courses usually followed by vessels. By reason of the expedition attained in deriving from these surveys the results of chief interest to mariners, it has been practicable for chart-publishing establishments to make prompt revision of defective sailing charts or to issue corrections thereto; and a distinct improvement in these aids to navigation is already noticeable in the charts issued by the leading maritime nations. The

more complete results of these ocean surveys are also in a forward state of preparation and it is expected that a full account of the work accomplished by the *Galilee* and the *Carnegie* will be ready for publication a year hence. In the near future it is considered that the *Carnegie* should make surveys in areas not yet covered and along some stretches already traversed where cloudy or stormy conditions have prevented the securing of adequate observations. She will at the same time cross her previous tracks as often as practicable in order to determine for such intersections the information now most needed by chart-makers, namely, the annual changes in the magnetic elements.

Magnetic surveys of land areas are also proceeding at a favorable rate. An expedition under Mr. D. W. Berky, assisted by Mr. H. E. Sawyer, has traversed the Sahara Desert, starting from Algiers near the end of October, 1912, and arriving at Timbuktoo May 12, 1913; and these observers are now extending their work into the territory of west and central Africa bordering on the Atlantic. Dr. H. M. W. Edmonds has led an expedition into Canada, west of Hudson Bay, near the location of one of the supposed poles of the earth's magnetic field. Mr. A. D. Power has made noteworthy progress in a survey of northeastern South America, including a trip along the Orinoco River and the Rio Negro from the mouth of the Orinoco to Manaus on the Amazon. Mr. H. F. Johnston is engaged in a series of determinations along a line running northward from Montevideo towards Manaus. Similarly, the magnetic survey of Australia and the adjacent islands is making efficient progress under the immediate charge of Mr. E. Kidson. Under his guidance Mr. E. K. Webb was trained for and supplied with instruments for the valuable magnetic work accom-

plished by the Mawson Antarctic expedition.

In the near future it is anticipated that the department will have sufficient data to permit the construction of a new set of magnetic charts, including all three magnetic elements (declination, dip and intensity), especially for that part of the globe included between the parallels of 50° north and 50° south of the equator. It will then be practicable to study the general problem of the earth's magnetism by aid of a large mass of homogeneous data surpassing in definiteness any mass hitherto available for this purpose. In anticipation of the need of experimental facilities for studies of this problem and others closely related thereto the office and laboratory building of the department was authorized a year ago and is now approaching completion, as explained in a previous section of this report. For the conduct of experimental researches the department has been fortunate in securing the services of Dr. W. F. G. Swann, late of the University of Sheffield. Mr. Charles R. Duvall, late of the U. S. Coast and Geodetic Survey, has also recently joined the office staff to fill the position of chief computer.

Attention is invited to the director's remarks on the present status of the department's work, to the account of his own researches of the year, and to his programs for further work. And in the interests of further possible work of construction of buildings under the auspices of the institution, it may be worthy of note that preliminary plans for the new laboratory were well matured by Mr. Fleming, engineer of the departmental staff, before consulting an architect, and that supervision of construction has also been assigned to Mr. Fleming. This method of procedure, which has been followed in several instances by the institution, appears to be highly advantageous for economy and for efficiency.

THE SOLAR OBSERVATORY

From the date of its establishment nine years ago this observatory has been one of the most important of the enterprises fostered by the institution. It has called for heavy annual appropriations; it has grown with extraordinary rapidity and with equally extraordinary productivity; and it is now an organization whose staff of investigators, research associates and collaborators, constructors, computers, designers, mechanics and operators includes upwards of sixty individuals. By reason of the widespread popular and technical attention given to astronomical science, and by reason of the novel equipment of this observatory and the relatively new field entered by it, the world looks with special interest on its development, quite apart from the keen general interest in the contributions it has made and may be expected to make to astrophysics. This special interest centers in the fact that the experience of the observatory furnishes the details of an experiment on a large scale in a difficult field of inquiry, for which ways and means of corresponding magnitudes have been available. In general the means at hand for such enterprises have been incommensurate with the obstacles to be overcome, and progress has been hindered, delayed or blocked until necessity has devised some indirect way of surmounting these obstacles. But, on the other hand, this necessity has hitherto exerted a highly beneficial influence in stimulating discovery and invention, and one may perhaps question whether in the past ampler means for the pursuit of systematic research would have been on the whole advantageous for the advancement of knowledge. Some eminent authorities, indeed, still question the propriety of the endowment of research in any but educational establishments. Contemplative minds

are therefore awaiting the results of the experiment of the solar observatory with an eagerness only exceeded by that of the popular mind for information concerning the latest discoveries and advances in astronomical science.

In the meantime, with the installation of additional equipment and the application of appropriate methods of research, the observatory is increasingly productive. The principal results of the work of the past year are summarized by the director in his current report under seventy-two heads. No further summary of these results may be attempted here; attention may be given to a few only of the salient items of interest suggested by the report as a whole. The year has been one of minimum solar activity and noteworthy for a nearly complete absence of sun-spots. This has proved advantageous for the pursuit of studies of the sun's magnetism now definitely proved by work done at the observatory during the year. This advance in solar physics is of the highest interest by reason of its probable relations to terrestrial magnetism and to cosmic physics. Stellar and laboratory work have gone forward at a highly productive rate, and the subjects of solar, stellar and laboratory spectra and stellar velocities are among those instructively considered in the director's report. Evidence has been accumulated tending to show that light is absorbed in space, and that such a phenomenon will not only elucidate others hitherto obscure, but furnish means of measuring the greater depths of the visible universe. Professor Kapteyn has continued to act as research associate and adviser in the program of researches undertaken. The important results attained by Professor Störmer, who spent some time at the observatory as a research associate in 1912, in his investigation of solar vortices, and

those of other collaborators and members of the observatory staff, present features of special interest in the departmental report.

Favorable progress has been made in grinding the glass disk for the 100-inch telescope since the source of the obstacle encountered in this work was discovered about a year ago. The disk has been subjected to severely critical tests, which give assurances that it will meet requirements. The preparation of a 60-inch plane mirror for testing the 100-inch reflector has gone on simultaneously with work on the latter. The heavier parts of the mountings for the telescope are now under construction by the Fore River ship yards at Quincy, Massachusetts, while the foundations on Mount Wilson and the dome superstructure will probably be completed as soon as the disk and its mountings are ready. Allusion has already been made in a previous section to the new office building at Pasadena and to the remarkable success achieved in the construction of a dividing engine for ruling diffraction gratings. For adequate accounts of these and numerous other subjects of interest reference must be made to the director's full report.

WORK OF RESEARCH ASSOCIATES AND COLLABORATORS

As indicated in previous reports, the complexity of the relations which research associates and collaborators sustain to the institution is so great as to preclude any comprehensive explanation within the limits allotted to an annual administrative report. Their work embraces a wide range of subjects and varies in its conduct from individual independence to intimate collaboration with the departments of research and with the division of publications. During the past year more than twenty distinct

fields of research have been cultivated and a total of more than one hundred investigators have contributed to the output. Summaries of the work of associates proceeding independently are given by them in the current year book. Their publications of the year are cited in the bibliographical lists of later sections, and the work of many collaborators is mentioned in departmental reports. Attention may be called, among many important researches, to that of Professor H. N. Morse on the osmotic pressure of solutions, now approaching completion; to the investigations of Professor Mall and colleagues in embryology; to the completion of the edition of the *Arthurian Romances* by Dr. H. Oskar Sommer by the publication during the year of the seventh volume of this monumental contribution to early English literature; to the appearance during the year of a translation into German of the work on "Dynamic Meteorology and Hydrography," the institution's publication No. 88, by Professor V. Bjerknes; to the significant studies of Professors Osborne and Mendel in extension of their researches on the vegetable proteids; to the fundamental investigations of Professor Reichert, brought out in publications Nos. 116 and 173; and to the penetrating contributions to philology embodied in the series of researches of Mr. William Churchill, published in Nos. 134, 154, 174 and 184.

FINANCIAL STATEMENT FOR FISCAL YEAR 1912-1913

The sources of funds available for expenditure during the past fiscal year, the allotments for the year, the revertments made during the year, and the balances unallotted and unexpended at the end of the year are shown in detail in the following statement:

Object of Appropriation	Balances Un- allotted Oct. 31, 1912	Appropriation Dec. 13, 1912	Reversions Nov. 1, 1912, to Oct. 31, 1913	Total	Aggregates of Allotments and Amounts Expended and Transferred	Balances Un- allotted Oct. 31, 1913
Large grants.....		\$816,972	\$21,287.75	\$838,259.75	\$838,259.75	
Minor grants.....	\$6,213.49	116,800	8,229.48	131,242.97	125,980.41	\$5,262.56
Publications.....	16,881.18	60,000	5,315.33	82,196.51	66,693.30	15,503.21
Administration.....		50,000	5,000.00	55,000.00	55,000.00	
Reserve fund.....		250,000		250,000.00	250,000.00	
Insurance fund.....		25,000		25,000.00	25,000.00	
Total.....	23,094.67	1,818,772	39,832.56	1,381,699.23	1,360,933.46	20,765.77

The following list shows the departments of investigation to which the larger grants were made by the trustees at their last annual meeting and the amounts allotted from these grants by the executive committee during the year:

Department of Botanical Research.....	\$38,005.00
Department of Experimental Evolution.....	95,141.75
Geophysical Laboratory.....	78,000.00
Department of Historical Research.....	29,600.00
Department of Marine Biology.....	31,890.00
Department of Meridian Astrometry.....	25,180.00
Nutrition Laboratory.....	46,549.00
Division of Publications (office expenses).....	9,000.00
Solar Observatory.....	165,631.00
Department of Terrestrial Magnetism.....	210,263.00
Researches in Anthropology.....	7,000.00
Researches in Embryology.....	15,000.00
	\$751,259.75

The fields of investigation to which minor grants were assigned, the names of the grantees, and the amounts of the grants are shown in the following list:

Field of Investigation	Names of Grantees	Amounts of Grants
Astronomy.....	Kapteyn, J. C.....	\$2,000.00
Archeology.....	Bandelier, Adolf F.....	2,000.00
	Van Deman, E. B.....	1,800.00
Bibliography.....	Index Medicus.....	12,500.00
Biology.....	Riddle, Oscar.....	5,600.00
	Watson, John B.....	500.00
Botany.....	Britton, N. L., and J. N. Rose.....	6,900.00
Chemistry.....	Acree, S. F.....	2,000.00
	Baxter, G. P.....	1,500.00
	Osborne, T. B., and L. B. Mendel.....	15,000.00
	Jones, H. C.....	3,200.00
	Forse, H. N.....	4,000.00
	Noyes, A. A.....	3,000.00
	Richards, T. W.....	3,000.00
	Sherman, H. C.....	1,200.00

Geology.....	Chamberlin, T. C.....	4,000.60
	Moulton, F. R.....	2,000.00
History.....	Osgood, H. L.....	1,200.00
Literature.....	Bergen, Henry.....	1,800.00
Marine Biology.....	Drew, G. Harold.....	2,000.00
	Vaughan, T. Wayland.....	3,300.00
Mathematics.....	Morley, Frank.....	1,200.00
Metallurgy.....	Howe, Henry M.....	500.00
Meteorology.....	Bjerknes, V.....	1,800.00
Nutrition.....	Tigerstedt, Carl.....	1,000.00
Paleontology.....	Case, E. C.....	2,000.00
	Hay, O. P.....	3,000.00
	Wieland, G. R.....	3,000.00
Paleography.....	Loew, Elias A.....	1,800.00
Physics.....	Hayford, J. F.....	2,000.00
	Nichols, E. L.....	3,000.00
	Barus, Carl.....	500.00
Physiology.....	Cooke, Elizabeth.....	1,900.00
	Reichert, E. T.....	1,500.00
Zoology.....	Castle, W. E.....	1,000.00
	Naples Zoological Station.....	1,000.00
Administration	Building (ad- ditions).....	5,792.66
Reception, National Acad- of Sciences.....		1,000.00
International Phytogeo- graphical As- sociation.....		1,200.00
		\$111,692.66

The following grants for publication were authorized during the year:

Andrews, C. M.....	\$2,006.22
Barus, Carl.....	900.00
Benedict, F. G., and E. P. Cathcart.....	2,200.00
Bergen, Henry.....	170.00
Cannon, W. A.....	2,000.00
Case, E. C., S. W. Williston, and M. G. Mehl.....	1,200.00
Castle, W. E., and C. C. Little.....	2,100.00
Castle, W. E., and J. C. Phillips.....	650.00
Davenport, C. B.....	800.00
Churchill, William, and J. P. Finley.....	2,000.00
Huntington, E.....	3,800.00
Index of U. S. Documents relating to	

Foreign Affairs	12,000.00
Jones, H. C.	1,400.00
Jones, H. C.	1,500.00
MacDowell, E. C., and W. E. Castle	600.00
MacDougal, D. T., <i>et al.</i>	4,200.00
Osgood, C. G.	9,000.00
Papers from the Tortugas Laboratory..	3,800.00
Reichert, E. T.	1,094.68
Shreve, Edith B.	700.00
Smith, E. F.	4,800.00
Sommer, H. O.	6,500.00
Walcott, C. D.	272.40
Weed, L. H.	1,600.00
Wright, Albert Hazen	1,400.00
	<u>\$66,693.30</u>

The sources and amounts of the revertments from November 1, 1912, to October 31, 1913, inclusive, are shown in the following list:

Large grants:

Transferred from minor grants	\$3,287.75
Revertment, Division of Publications	3,000.00
Revertment, Department of Meridian Astronomy ..	<u>15,000.00</u>

\$21,287.75

Minor grants:

Cooke, Elizabeth, Grant No. 878	550.00
Drew, G. Harold, Grant No. 854	2,000.00
Fitting, Hans, Grant No. 816 ..	1,800.00
Historical Research, Department of, Grant No. 794	90.00
Osborne, T. B., Grant No. 692	83.32
Reception, National Academy of Sciences, Grant No. 879 ..	381.16
Terrestrial Magnetism, Department of, Grant No. 798	25.00
Vaughan, T. Wayland, Grant No. 855	<u>3,300.00</u>

8,229.48

Publication:

Barus, Carl, Grant No. 872 ..	353.50
Benedict and Jones, Grant No. 820	284.00
Bergen, Henry, Grant No. 826	<u>7.13</u>

Administration:

Revertment from allotted balance	5,000.00
	<u>\$39,832.56</u>

R. S. WOODWARD

EDUCATIONAL INTERESTS AT WASHINGTON

I

ONE of my first impressions when I joined the Federal Bureau of Education at Washington, in the summer of 1906, was that of the cooperative friendliness of the various executive offices with which I had to do. Every door was open. My new-found colleagues in the Department of the Interior and its other bureaus, the higher officials of three or four other departments, with whom the business of my office soon brought me into contact, the public printer, the civil-service commissioners, the director of the census, officials of the Smithsonian Institution, the librarian of Congress, the White House staff, and the President himself—all were not only easy of access, but were prompt to welcome the newcomer and to lend him a helping hand.

On the day that I entered upon my new duties, the thermometer in my office registered 95°. The rest of the summer was steaming hot. It rained on St. Swithin's day and—more or less—for forty days thereafter, and the sticky heat was well-nigh unbearable. But the warmth of welcome which I experienced at the hands of members of the administration who were still on duty at the Capital did much to make that external heat and humidity endurable.

I began, indeed, to wonder whether the difficulties of which I had been warned were not imaginary. Here was none of that immobility of the great governmental machine of which I had heard so much. It was not until the eve of the assembling of Congress that the other side of the picture was fairly exposed. On Thanksgiving Day I was summoned before the House Committee's sub-committee on the "legislative" appropriation bill, for my first annual hearing on the estimates for the bureau for the next ensuing fiscal year. Then I knew. No great advance could be made in the usefulness of the education office without increase of appropriations; and there was evidently in Congress an intrenched tradition that the federal government should not go deeply into expenditures for public education.

In order to be quite fair, some qualifications must, of course, be made. The contrast in attitude between the executive and the legislative branch of the government was not that between white and black but that between light gray and a misty dimness.

Not everything was easy on the administrative side. There were some difficulties that were internal to the bureau. Such were, of course, inevitable. They were, however, made good in part by the loyal support of competent men and women on the staff of the office.

I may go out of my way just here to pay tribute to my venerated predecessor in the commissionership, Dr. William T. Harris. He had presided over the Bureau of Education so long, and with so dominating a personality, that in a sense it had become his own. He continued his residence in the city of Washington. He was a veritable mine of information and judgment regarding the bureau in all of its relationships. Yet from the moment that he laid down his official responsibility, he did not seek in any particular to direct or even to influence the administration of his successor, while giving at all times a friendly sympathy and support that was, to the younger man, of immeasurable value.

Secretary Ethan Allen Hitchcock was at the head of the Department of the Interior. I soon found some justification for the saying that he counted every man guilty till he should have proved himself innocent. The delicate question here was the management by the bureau of the reindeer annex to its provision for the education of the Alaskan natives. This branch of the service was in a peculiarly perplexing situation just then. When President Roosevelt had called me to Washington, to offer me the post of commissioner, his talk had hardly touched upon any other side of the bureau's activity. While the secretary's attitude on this subject for a time increased the difficulty of the situation, and a solution was not reached until he had been succeeded in the portfolio by Mr. Garfield, I entertained, nevertheless, and still retain, something like historic veneration for the really Roman personality and service of Secretary Hitchcock.

One of my earliest attempts to widen the service rendered by the education office brought me into interesting relations with an assistant secretary. He was the acting head of the department during the temporary absence of his chief. What I sought

to do was to publish a bulletin of miscellaneous educational information, to be put forth in occasional issues, as matter of practical value should become available. When I broached this plan to my associates in the bureau, one of them, having a long memory, called my attention to an obscure clause in an Act of Congress already ten years old, which expressly provided for such a publication. This was encouraging. But there was no appropriation to cover the cost of printing. As in the case of other miscellaneous printing for this office, an allotment must be secured from a general appropriation for printing in the Department of the Interior, and that was under the secretary's immediate control.

I laid the case before the acting secretary, calling his attention to the fact that the proposed publication had already been authorized by Congress, and also that it would enable the bureau to discharge more effectively one of the chief functions assigned to it in the Act for its establishment, namely, that of distributing educational information. He had himself been a member of Congress. He listened to my statement most courteously, and then replied that the thing could not be done. The money was needed for other uses.

There was, fortunately, present at the interview one of the indispensable men of the department. A fair number of such men are to be found distributed through the several branches of the government—men of sane judgment, possessed of unlimited and accurate information, devoted to the interests which their several offices serve, and free from that form of ambition which would prompt them to intrigue for their own advancement. There is no reason why I should not make individual mention of Mr. W. B. Acker, to whom I have referred. I doubt not he is still serving the public from that piled-up desk of his;

and I hope the public will long enjoy and appreciate his services.

I had already consulted him with reference to my little publication plan. The acting secretary glanced toward his subordinate when pronouncing his adverse decision. Most tactfully then the under official reminded the high official that the very modest sum required could be spared without appreciable detriment to any other interest, and that the legality of such use of the fund was beyond question. With only two or three sentences, the scale was turned. The expenditure was approved, and the preparation of the first issue of the bulletin was immediately begun.

I believe the publication has been a useful one from the start, and it is now having a great development at the hands of Commissioner Claxton.

A few such experiences as that described above led me to the all-too-hasty generalization that if a public official desired to do anything new in Washington, he would either find that it is already in the law of the land, or that it is impossible—and sometimes both at once.

With other assistant secretaries, and indeed with the one referred to above, I had other relations in plenty which I can recall only with warm appreciation and gratitude.

But to come back to the legislative side of the matter. Here, again, I must avoid too sweeping a statement. In the matter of appropriations, I fared as well as my predecessors or perhaps a little better. Including the provision for the Alaska work, the appropriations were increased in those five years by about 68 per cent. This would not be so bad a showing, were it not that the total amount was pitifully small as compared with the magnitude of the interests and needs involved. For the year 1911-1912, the appropriation for the

Alaska work was \$212,000, and for all of the rest of the activities of the bureau only \$79,800, to which there should be added an allotment from the secretary's fund for printing amounting to \$50,000.

I was early impressed with the fact that it was easier to get appropriations for the education of the natives of Alaska than for the bureau's ordinary work of collecting and diffusing information. At the first session of Congress after I had entered the bureau, through the active interest of Mr. Tawney, then chairman of the House Committee on Appropriations, there was procured an addition of \$100,000 to the annual appropriation for the Alaska work. On the other hand, even small additions to the provision for collecting educational information, for the employment of competent experts in different branches of education, and so on, were secured only with the greatest difficulty.

II

It would seem, indeed, to be a fixed tradition in both Houses of Congress that the expansion of the education office shall be only gradual and comparatively insignificant. It has been shown, on the other hand, that at some time or other a rapid and considerable expansion will have to take place in order to bring up arrears, as it were, and enable the office to "start even" with its responsibilities. But that time is not yet in sight.

When one secretary of the interior made an active effort to secure increased appropriations, he was turned aside with the intimation that further legislation was necessary as a basis for such appropriations; and when this suggestion had been followed up and existing statutes had been found to cover the case completely, the session was too far advanced to secure the desired additions to the appropriation bill of that

year. President Roosevelt in his last annual message recommended a substantial increase, but without result. The National Education Association passed its resolutions, and made its personal representations through a strong committee, headed by President John W. Cook, of Illinois. Some three or four years ago a wide campaign, in which the Russell Sage Foundation bore an important part, was carried on with the purpose of arousing public interest and awakening in Congress a more serious attention to the needs of the bureau. Mr. Herbert Parsons seconded this effort with an able address on the floor of the House. The result was that there was granted about one tenth of what had been sought.

There are doubtless reasons for this comparative inaction on the part of the Congress. I shall not undertake to canvass them here. But a word may be said concerning one objection frequently heard, namely, that education belongs to the states, and lies outside of the proper sphere of the federal government. It does not appear that any such objection lies against the main activity of the Bureau of Education, which is not that of educational administration at all, but that of disseminating useful information. The objection, moreover, can hardly be taken seriously as against activities which have been maintained by Congress for nearly fifty years. Each renewal of its appropriations for such activities has been a fresh assertion of the right to carry them on, and each small increase of those appropriations has laid new emphasis upon that assertion.

A comparison of the history of the Department of Agriculture with that of the Bureau of Education is instructive. Both of these offices have to do with interests which some would regard as falling within the range of the state governments, rather

than within that of the federal government. Both of them are concerned chiefly with the spread of information rather than with administrative control. Both came into being with the great advance of nationalism in the decade of the Civil War. The Department of Agriculture was established as an independent department in 1862, with a commissioner at its head, and without representation in the cabinet. After making its way against great difficulties for many years, it became a fully organized department of the government in 1889, its head becoming a member of the President's cabinet. The Bureau of Education, on the other hand, first organized as an independent department, without cabinet representation, in the year 1867, was transformed into a bureau of the Department of the Interior in 1869, and that has been its status down to the present time. The movement of congressional appropriations for these two offices is shown side by side, at ten-year intervals, in the following table:

	Department of Agriculture	Bureau of Education (including after 1880 the Alaska Service)
1870	156,440	5,400
1880	201,000	26,995
1890	1,669,770	104,920
1900	3,726,022	116,270
1910	12,995,274	284,200

Three years later the annual appropriation for the Department of Agriculture had advanced to \$22,894,590.

It may not be altogether fanciful to suggest that one reason why Congress is reluctant to enter upon any considerable increase of appropriations for the education office is a fear of the breaking loose of another avalanche of expenditure like that for the agricultural department. However, when one looks upon the great contribution which that department has made to our national prestige and prosperity, it will

be seen that this is a consideration which may cut both ways.

For my own part, I have no doubt that when we get any clear vision of the meaning of science and education and the arts in our national life, we shall have liberal appropriations for these objects from the federal government; and that any interpretation of the limitations upon the federal government which would stand in the way of such appropriations, will then be regarded as fanciful and "academic."

No one can foretell how that vision will come to the American people. It is, in fact, slowly dawning at the present time. But its coming must be accelerated, or we shall have long to wait. One thing that may be expected to quicken our national insight in this regard is the growing pressure of international competition, especially in the field of commerce and industry. The opening of the Panama Canal will open the eyes of the American people in unexpected ways. Then, too, the political movement toward democracy and more democracy, as represented by direct primaries and other new forms of governmental apparatus, is making a nation-wide demand for heightened efficiency in our educational systems. Not long ago, this last-mentioned view was presented with great clearness by Senator Burnham, of New Hampshire. There are other tendencies of our time which are carrying us surely in the same direction. Our country simply can not make itself what it would be, both at home and abroad, without more of national emphasis upon the education of the whole people, and upon that advance of science and the arts on which both modern education and modern government depend.

III

In this paper I have drawn freely upon my own recollections, simply as straws in-

dicating the way the wind has blown in recent years at Washington. And I have ventured to forecast a change of weather which must sooner or later affect our national education. Sooner rather than later, I think, but I am not a prophet, to foretell the day and the hour. Now, in the space which I may still use, I should like to offer a few brief suggestions regarding the form which our new national education may be expected to take.

The question is much larger than that as to the future of the Bureau of Education. Its principal elements are those relating to a national university, to federal aid for elementary schools, to the promotion of agricultural and other technical education in secondary and higher institutions; and finally those relating to the Bureau of Education, which must, after all, have an important place of its own in the general scheme. We pass over the military and naval academies, the schools for Indians, and other special educational undertakings in which our government is engaged; and this paper must be limited to the problem, as old as our federal government itself, of a national university. Here we shall try only to get some glimpse of the bare framework of a vast design.

There is one side of our whole national life and national government which is neither economic nor political but scientific, and must be scientifically discerned. The problem of a national university is the problem of the organization of this scientific side. In some few of the states it has been measurably recognized and organized in state universities. In our federal system it has been recognized fragmentarily, and as a result various special commissions and scientific bureaus have come into existence. What is lacking is a unitary organization. And that unitary organization is requisite in order that every piece of scientific work

done for the government may have back of it the whole force of established scientific method, standards, and processes, of scientific atmosphere and the ethics of science, which is realized only where many scientific departments work together long and continuously.

A special tariff commission or any other sudden and temporary scientific commission is a makeshift at the best. It will be found at length that what is needed, in place of these, is a continuous and many-sided study of wages, industrial conditions, and cost of production, the world over, carried on under conditions favorable to scientific progress, and in close connection with countless other inquiries with which these are interwoven.

We shall find, indeed, that a scientific branch of government, complete in itself, with its own traditions and its own methods, is as essential to the health of a modern nation as is a judicial branch, complete and sufficient in itself, and with its own juridical forms and procedure. It is necessary that this scientific side of our federal life be made a national entity, and given a fair opportunity of acquiring impressiveness and influence suited to its nature; and that is an opportunity of becoming a really commanding force in our national affairs in proportion to the service it is capable of rendering.

In concrete terms, this would involve a separation of those existing offices of the government which are chiefly investigational in their character from those which are chiefly administrative; the grouping together of those of the former class, under some convenient working system; and the organization of new divisions, somewhat similar in character to the scientific bureaus already in existence, in order to deal with new needs as these shall become apparent and urgent. The process may very likely

be a slow one; but it is a building for the centuries, and the movement toward a comprehensible end is the principal thing at the present time.

Among the offices and institutions to be brought together in this unique university would naturally be the Library of Congress, the permanent organization of the Census Office, the Geological Survey, the Bureau of Standards, the Naval Observatory, and possibly the more strictly scientific offices of the Department of Agriculture. The Bureau of Education should be included, so far as its typical activities are concerned, provision being made elsewhere for the discharge of its administrative functions. It does not appear that the special form of organization of the Smithsonian Institution would prevent it from being made a member of this central group, in which its membership, with that of the National Museum, would be of the utmost importance. If not incorporated in the new organization, it should at least be related to it through some close affiliation.

A very fair beginning might be made with such a group. It should be reasonably clear that a university so constituted at the outset would be different from any that the world has hitherto seen. It would indeed be an institution of national dimensions, as well as of national functions.

It is not to be supposed that the mere putting together on paper of these great government offices would make such a national university as is here proposed. The federal legislation which should bring them into one interlocking group would be but the bare beginning. The adjustment of their mutual relationships, the rounding out of the organization by the addition of needed departments and activities, the settlement of the relations of the university to other branches of the federal government and to educational systems and institu-

tions throughout the country—all of these things will call for imagination and foresight and administrative ability of the highest order. Under the authority and with the support of the Congress of the United States, the offices and governing boards of the new institution will have the responsibility of shaping a real organ of enlightenment, which shall not only be for all of the sciences and for all of the people, but shall be an effective working instrument as a whole and in its several divisions.

The relations of such a national university to other scientific foundations and institutions of learning, at home and abroad, will be of the utmost consequence. So far as American universities are concerned, its relations with them may have something of the "federal" character. It will not supplant them; it will not merely supplement them; to some extent, I think, it will have its existence in them, and they will be participants in its life.

As I conceive it, the national university will be a teaching body as well as an investigating body, but it will not confer any academic degrees. As a teaching body, it will escape the reproach of abstractness and lack of system which lies against some laboratories and bureaus of pure research. Its teaching courses, which must necessarily be of an advanced grade only, may be brought into very fruitful relations with a reorganized office for the federal civil service. On the other hand, to withhold from it the power to confer the traditional degrees, will be to emphasize its unique character, and in the end will add to its strength and influence. Let universities such as we now have, continue to celebrate their commencement occasions and bestow their beribboned diplomas, undisturbed by any federal competition. These things are not unimportant, but the institution that is here proposed will have other and rather

more weighty business. Nevertheless, it is inevitable that if its work be well done it will eventually become the foremost factor in determining the standard and the standing of American scholarship and American degrees before the nations of the world, and consequently before our own people here at home.

The investigation of a network of problems of labor, the costs of production, customs duties, commercial relations, and the regulation of corporations, will be one of the earliest undertakings which a national university may be expected to place upon a scientific basis. Its studies in this field will of necessity extend over decades and even generations. But within a few years there should be assembled and made available for use a greater body of digested information on these subjects than any Congress or administration in this country or any parliament or ministry abroad has ever had, on which to base its industrial legislation.

To amass information, however, is not of itself scientific. What is to be chiefly hoped is that from such researches, in which closely related sciences shall be cultivated together and all upon the largest scale, there shall emerge new and enlightening theories, embodied in new and well-grounded principles of social development.

Finally, if I have spoken thus far of the sciences only, it is not meant to the exclusion of the arts. Quite the contrary. In a more profound sense than is commonly believed, the arts are bound up with the sciences in the making of our civilization. Music, sculpture, and painting are, generally speaking, mere hangers-on in our scheme of higher education to-day. This is one of the defects in our university life which the nineteenth century has handed on to the twentieth. It is one of the defects which a national university should help us to correct. If we are to have anything like

national standards in our drama, in our fiction and our verse, in the aggregate architecture of our cities, in the fine arts generally—still more, if we are to make a disciplined sense of beauty sustain, correct, and supplement the scientific trend of our life—our national university must help us in this great work. At best, it is a slow work and a mighty. We shall do well if another century shall find us far advanced upon it.

What has been offered here is only the barest outline of a great hope and dream for our national life. It will seem far removed from those briefly jotted experiences with which this article began. It is a hope and dream which those experiences, however petty by comparison, did not in any measure dampen or abate. Indeed, while I had at Washington a keen sense of the disproportion between the work in which I was engaged and the work of that kind which this country imperatively needs, I went on in that work with a growing conviction that no greater or lesser performance of my own or of any other commissioner, no favoring or adverse attitude of successive secretaries, congresses, or presidents, can in the long run prevent this country from erecting its great national institution of education, science, and the arts, at least coordinate with the traditional branches of government, in which all systems and institutions of science, art, and education throughout the land shall be participants, and shall find therein a new realization of their best ideals.

ELMER ELLSWORTH BROWN

NEW YORK UNIVERSITY

*LOCAL BRANCHES OF THE AMERICAN
ASSOCIATION FOR THE ADVANCE-
MENT OF SCIENCE*

At the Atlanta meeting of the American Association for the Advancement of Science the following resolutions were unanimously adopted:

Resolved, That the council of the American Association for the Advancement of Science authorizes the establishment of local branches of the association in places where the members are prepared to conduct branches which will forward the objects of the association.

Resolved, That the standing committee on organization and membership be instructed to promote the establishment of such local branches.

The plan of regional division and local branches has been under consideration for some time. Last year a Pacific Coast division was established and an associate secretary for the south was appointed. At the Atlanta meeting a Brazilian division was authorized. There is every reason to believe that a forward step in the advancement and diffusion of science can be taken by the establishment of local branches, especially in places where there are no chapters of the Society of the Sigma Xi, academies of science, or similar organizations. Even where such agencies already exist, a union of the members of the American Association might cooperate with them for their common interests. A local branch can arrange for lectures, scientific programs, dinners and social meetings, which will bring together those interested in the progress of science, will encourage them in their work and improve the conditions under which it is done, and will increase the interest of the community in science. If a number of local branches are formed in a state or a region it will be possible to arrange for joint meetings or for a lecturer to address meetings in the different places.

The great increase in the number of scientific men, their scattering in this country over a vast area and the differentiation of their work have made it difficult or impossible for them to come together at national meetings and discuss their common objects. The advance and necessary specialization of science tend to divorce it from the interests of the people on whom in a democracy it must depend for recruits and for support. Local societies or clubs, especially in smaller centers where there are not enough scientific men to form groups of specialists and where lectures and scientific programs are not common, can

accomplish a great deal to maintain interest in research and to impress its importance on the general public. They will be aided by the prestige of the history and the national scope of the American Association with its eight thousand members and will in turn strengthen the work and influence of the association.

The standing committee of the association on organization and membership, of which Dr. W. H. Welch, of the Johns Hopkins University is chairman, the permanent secretary, Dr. L. O. Howard, is a member, and Professor J. McK. Cattell, Garrison-on-Hudson, N. Y., is secretary, has been authorized to promote the formation of such local branches and the secretary of the committee will be glad to correspond with members of the association who may be interested in the formation of local branches which will promote the objects of the association in their neighborhoods.

SCIENTIFIC NOTES AND NEWS

THE Senate has confirmed the nomination of Col. William C. Gorgas as surgeon-general of the United States Army.

DR. WALTER P. BRADLEY has resigned as professor of chemistry after twenty-five years of service at Wesleyan University to take charge of the investigations of the United States Rubber Company in whose employ he recently spent a year's leave of absence.

DR. EDWIN G. CONKLIN, professor of biology in Princeton University, has been elected a foreign member of the Royal Bohemian Academy of Sciences.

DR. SAMUEL AMBERG, of The Otho S. A. Sprague Memorial Institute Laboratory, of Chicago, has been elected a corresponding member of the Society of Internal Medicine and Pediatrics in Vienna.

DR. ADOLF FRANK, known for his important contributions to agricultural chemistry, celebrated at Charlottenburg, on January 20, his eightieth birthday.

PROFESSOR W. M. DAVIS, of Harvard University, plans to carry out an exploration of some of the coral islands in the Pacific. He is so arranging his tour as to be able to attend the

meetings of the British Association in Australia.

PROFESSOR E. W. BROWN, of Yale University, has accepted the invitation of the British Association for the Advancement of Science to attend the Australia meeting in 1914. He expects to be absent from the university until February, 1915.

DR. J. C. ARTHUR and Mr. F. D. Fromme, of Purdue University, are making a botanical trip through Texas, New Mexico and Arizona during the month of February. The special object of the trip is to obtain additional information on certain species of Uredinales, whose life histories are incompletely known.

PROFESSOR GEORGE B. RIGG, of the University of Washington, is absent on leave for the rest of the academic year. He is at the University of Chicago.

WALTER WALLACE WEIR has been placed in charge of cooperative drainage experiments being carried on at Kearney Park, near Fresno, on the 5,400-acre ranch belonging to the University of California. The University and the Office of Experiment Stations of the United States Department of Agriculture are making these investigations in the reclamation of alkali lands by drainage ditches and a pumping system.

We learn from *Nature* that Mr. J. I. Craig has been transferred from the directorship of the meteorological section of the Egyptian Survey Department to the controllership of the Department of Statistics, and has been succeeded at the survey by Mr. H. E. Hurst.

MR. W. LAWRENCE BALLS, botanist to the Egyptian government, Department of Agriculture, has left the service and is returning to Cambridge to work up the data on cotton which he has collected.

DR. EMIL ABDERHALDEN, professor of physiology at the University of Halle, will lecture at Columbia University next autumn.

PROFESSOR DANA DURAND, of the University of Minnesota, formerly director of the United States Census, will lecture at Harvard University in April on combinations and trusts.

PROFESSOR D. W. JOHNSON, of Columbia University, recently gave an illustrated lecture before a joint meeting of the American Scenic and Historic Preservation Society and the American Museum of Natural History on the subject "The Scenery of the Atlantic Coast and Its Answer to the Question: Is the Coast Sinking?"

PROFESSOR WALDO H. NORRIS, of Grinnell College, will lecture on zoology at Harvard University this term under the exchange agreement with colleges of the middle west.

DR. W. P. MASON, professor of chemistry in the Rensselaer Polytechnic Institute, lectured on January 29, before the Franklin Institute of Philadelphia, on advantages and disadvantages of water storage.

DR. JOHN P. STEWART, professor of experimental pomology of the Pennsylvania State College, during the current fall and winter has lectured before the Maine State Pomological Society, the Massachusetts Fruit Growers' Association and the New Hampshire State Agricultural Convention on "The Results of Seven Years' Experiments with Different Cultural Methods, Covercrops and Fertilization in Apple Orchards."

DR. W. B. SCOTT, Blair professor of geology and paleontology at Princeton University, is giving a course of six lectures on the theory of evolution before the Wagner Free Institute of Science, Philadelphia. The lectures which are given on Saturday evenings are on the Richard B. Westbrook Free Lectureship.

DR. DAYTON C. MILLER, professor of physics in the Case School of Applied Science, has delivered before the Lowell Institute, Boston, a series of eight lectures, the subjects of which were as follows: January 20, Sound, Sound Waves, Character of Sounds; January 23, Pitch, Loudness, Tone Color, Pure Tones; January 27, Methods of Recording and Photographing Sound; January 30, Effects of Horn and Diaphragm on Sound; February 6, Tone Qualities of Various Musical Instruments, Ideal Tone; February 10, Physical Characteristics of Vowels and Other Sounds of Speech; February 13, Synthetic Reproduction of the

Tones of Instruments, of Vowels and Spoken Words.

At the College of Medicine of the University of Illinois, Chicago, Drs. Bartlett, Burmeister, Davis, Dreyer, Eycleshymer, Falls, Fantus, Hartung, Miller, Moore and Welker recently organized a medical research club of the University of Illinois. Dr. D. J. Davis was elected president, and Dr. Wm. H. Welker was elected secretary for the balance of the college year. Dr. Eycleshymer presented a paper entitled, "Some Observations on the Decapitated Young *Necturus*."

THE *British Medical Journal* understands that arrangements have nearly been completed for the establishment, as a memorial to Lord Lister in Edinburgh, of a Lister Institute. It is proposed that the institute, which will be devoted mainly to research in bacteriology and pathology, shall work in connection with the university, but that it shall be managed by an independent board consisting of representatives of the Royal Colleges of Physicians and Surgeons, and of the university, and probably of the Carnegie trustees, who have recently become interested in the laboratories of the Royal College of Physicians. It is intended that certain facilities for teaching shall also be provided. It would appear to be the intention that eventually all pathological work, both in research and teaching, in Edinburgh shall be under the general supervision of the professor of pathology, who, in addition to holding that chair and taking an appropriate share in the conduct of the new institute, will act as honorary pathologist to the Royal Infirmary.

DR. WILLIAM KELLY SIMPSON, professor of laryngology at the College of Physicians and Surgeons, Columbia University, died on February 6, aged fifty-eight years.

DR. K. H. F. ROSENBUSCH, formerly head of the geological-mineralogical laboratory at Heidelberg, distinguished for his contributions to mineralogy, has died at the age of seventy-eight years.

DR. FELIX HAHNSCHAFTE, professor of geology in the Berlin Mining Academy, has died at the age of fifty-three years.

THE U. S. Civil Service Commission announces an open competitive examination for assistant chief, Bureau of Chemistry, to fill a vacancy in this position in the bureau of chemistry, Department of Agriculture, at \$4,000 a year. It is desired to secure the services of a man of broad training and extensive practical experience in physiological chemistry and medicine as well as experience as an administrative officer to assist in the research and supervisory work of the bureau of chemistry, and the enforcement of the food and drugs act. Applicants will not be assembled for examination, but their relative qualifications will be rated upon the evidence adduced as to their education and training, practical experience and fitness, and their publications. Applicants must give in their applications a complete statement of their educational training, a complete statement of their practical experience, and a list of their publications. Copies of such publications should be filed with the application. An educational training including an M.D. degree from a medical school of recognized standing and special training in analytical and physiological chemistry other than that included in the medical course; and not less than three years' experience as a medico-legal expert, and some experience as an administrative officer, are prerequisites for consideration for this position. Applicants must have reached their thirtieth but not their forty-fifth birthday on the date of the examination.

UNIVERSITY AND EDUCATIONAL NEWS

BOWDOIN COLLEGE has received a bequest of \$500,000 for the general fund of the college from the estate of Edwin B. Smith, former assistant attorney general of the United States, who died in New York on January 5.

YALE UNIVERSITY receives \$500,000 under the will of Lord Strathcona and Mount Royal, who died on January 21. The Royal Victoria College at Montreal, a girls' school, is given \$1,000,000. Lord Strathcona leaves to St. John's College, Cambridge, \$50,000; to the University of Aberdeen, for the creation of a chair of agriculture, \$25,000; to the Presby-

terian College at Montreal, \$60,000, and to Queen's University, Kingston, Canada, \$100,000. In addition to this sum he bequeathed to the Royal Victoria Hospital at Montreal \$500,000, and to hospitals in the British Isles, \$90,000. The bequest to Yale University is

for the promotion of the modern sciences, and for instruction in the practical questions arising from the application of scientific knowledge to the industrial, social and economical problems of the times, it being my special desire to have the said sum expended so far as in the opinion of my trustees may be deemed advisable for instruction in civil and mechanical engineering, with special reference to the construction, equipment and operation of transportation of passengers and freight, whether by land or water, and the financial and legislative questions involved.

THROUGH the will of the late Mrs. Elizabeth Mattox, of Terre Haute, the sum of \$45,000 will be added to the general endowment of De Pauw University.

MRS. WILLIAM PORTER HERRICK, widow of the late William Porter Herrick, has given to the University of Colorado, \$5,000, to be used as an aid fund for worthy students.

SIR HILDRED CARLILE, M. P., has given \$500,000 to Bedford College, London, as a memorial to his mother, Mrs. Edward Carlile.

DR. HUGO FROMMSDORFF, on the occasion of the fiftieth anniversary of his doctorate, has given \$5,000 to the University of Heidelberg for a foundation for the advancement of chemistry.

ACCORDING to the daily press President Edmund J. James, of the University of Illinois, called, on February 3, a meeting of the faculty and announced that he had received reports that he did not possess the confidence and support of the faculty without which he did not wish to retain the presidency. The faculty in secret ballot by a vote of 188 to 4 declared confidence in President James.

It is announced that Dr. Frank J. Goodnow, Eaton professor of administrative law and municipal science at Columbia University, at present constitutional adviser of the Chinese Republic in Peking, has been offered the presidency of the Johns Hopkins University.

DR. M. A. BRANNON, professor of biology in the University of North Dakota and dean of the college of liberal arts, has been elected president of the University of Idaho.

DISCUSSION AND CORRESPONDENCE

LABELLING MICROSCOPIC SLIDES

WITHIN the last year or so SCIENCE has published four short articles on labelling slides.¹ From this it would seem to be a subject of some interest. I have therefore ventured to add a method which I have been using with entire satisfaction for some time past.

The objections to scratching slides or other glassware with a diamond or carborundum is that the label can not be removed, if for any reason this is necessary. Another objection that is equally serious is the difficulty of making clear and legible labels where several words must be written. These reasons led me to abandon this method long ago.

Marking with wax pencils is of doubtful value owing to the extreme care necessary to avoid removing the label through contact with xylol or by mere rubbing. My own experience with waterproof ink has been that it is also too easily rubbed off or washed off while passing slides through water or aqueous stains.

Etching or grinding the surface of the slide is satisfactory where the surface thus prepared is to be used frequently but is entirely too troublesome for ordinary slides. Moreover, the pencil label is not always easily legible.

I now use an ordinary india ink (l'encres de chine) to which I have added a little ordinary water glass (sodium silicate solution) such as is sold at the corner drug store for preserving eggs. It is usually better to thin, after adding the water glass, with enough water to make the ink flow freely. With this ink one can write with a fine pointed pen any label that he

¹A. F. Blakeslee, "A Labelling Surface for Glassware," SCIENCE, 37: 561, 1913; Zae Northrop, "A New Method for Labelling Microscopic Slides," SCIENCE, 38: 126, 1913; Ernest Shaw Reynolds, "Labelling Microscopic Slides," SCIENCE, 38: 363, 1913; Frank E. Blaisdell, "Labelling Microscopic Slides," SCIENCE, 38: 665, 1913.

would have been able to write on paper. It can be put on the slide as soon as the paraffin ribbon has been mounted. If the slide was clean when the label was written, water, alcohol and xylol may be applied to it freely without any danger of injury. Ordinary abrasion such as the slide frequently encounters in use will not in any wise affect the permanency of these labels. They can, however, be scratched off easily with a dull knife (or scrubbed off with scouring soap). A white paper label pasted on the *back* of the slide will make it even more conspicuous.

SCIENTIFIC BOOKS

Mathematical Monographs. Edited by MANSFIELD MERRIMAN and ROBERT S. WOODWARD. No. 12. *The Theory of Relativity.* By ROBERT D. CARMICHAEL. New York, John Wiley & Sons. 1913. Pp. 74.

Unlike most presentations of the theory of relativity, which contain a considerable amount of technical mathematical physics, Carmichael's is non-technical and logical in the same way that the discussion of the foundation principles of geometry or mechanics or chemistry might be made non-technical and logical. The book may, therefore, be read with ease by the mathematician who has little or no knowledge of modern physics or by the physicist

¹ Smithsonian Miscellaneous Collections, Vol. 56, No. 85, p. 1, February 7, 1912.

² Linne's "Natarsystem," Vol. 2, p. 481, 1808.

who is unacquainted with mathematical analysis; it might be read by the engineer or, for the most part, by the philosopher. The work is in no sense a mere compilation from the investigations of previous authors, but represents a considerable amount of independent investigation of which the major part has appeared in contributions to the *Physical Review*.

The strongest and most satisfactory part of the book is that dealing with the statement of the postulates upon which the theory is built and with the direct consequences of the postulates. Less final and satisfactory are those parts where the physical theories (as distinguished from the results of physical experiments) which might conceivably underlie the theory are mentioned. This lack of finality and satisfaction is, however, quite unavoidable in these latter days when so many phenomena apparently subversive of long-accepted notions are constantly being unveiled. One has only to read the report on "La Théorie du Rayonnement et les Quanta,"¹ of the colloquium held at Brussels in 1911 to see in what a state of partial bewilderment and contradiction are the leading physicists of our time. The riot of new hypothesis and theory in the last volume (No. 26) of the *Philosophical Magazine* is a similar indication.

The author abstains from electromagnetic theory and confines his attention to the relation of the theory of relativity to the concepts of length and time, of mass and energy; he has, however, to mention that fundamental unit of electricity, the electron. He does well to emphasize the independence of the theory of any hypothesis as to the existence or non-existence of the ether, even though he subsequently finds it useful to make use of the ether in discussing the physical nature of mass. He could profitably have gone a little more into detail with regard to the relation between the ether and relativity.

Once we admit the existence of a stagnant ether, we have at hand at least a logical fixed system of reference; we may logically speak of

¹ Langevin and Broglie, Gauthier-Villars, 1912.

absolute motion, even though we may be unable experimentally to determine the absolute motion; the change of mass and of length which arise in moving systems are then but the natural consequences of the redistribution of the lines of force issuing from the moving charges; our concept of time and distance is no longer in need of modification; we have essentially the original Lorentz point of view. The theory of relativity then is merely a collection of results interpreted on moving axes (with local time) and abstracted from the underlying ether; the fundamental postulate M of the theory, that we can not detect absolute motion, is a natural consequence of the fact that the transformations between different sets of moving axes (and times) form a group. For instance, if two particles move in different directions through the ether each is actually shortened in the direction of motion, but observers attached to the particles can observe no shortening because everything in the system is similarly shortened. And moreover, since the transformations above mentioned form a group, each observer, abstracting from any conception of the ether and experimentally unaware of any shortening in his system, concludes that the system of the other observer is shortened in the direction of their relative motion and by the amount appropriate thereto.

On the other hand, if we take the point of view that what we can not directly observe does not exist, if we take the theory of relativity as itself fundamental and banish the ether, then we have no such physical or conceptual basis upon which to explain the shortening, the alterations in mass, or the changes in time, and we are forced to change our concepts of mass, length and time; we are forced to all those new ideas which the theory of relativity brings in and which seem incongruous or bizarre to many persons, and these ideas assume a semblance of naturalness only when our universe is interpreted as four-dimensional with space and time unified and inherently interrelated, in the manner adopted by Minkowski or Wilson and Lewis or McLaren. Which of the two points of view we adopt depends largely upon our turn of mind.

There are philosophers who feel that we are entirely free to construct for ourselves any image of the physical universe which seems most natural and easy; they will probably hold to the ether as long as possible. There are others who feel that we should not intrude into the image any ideas which represent things not immediately subject to experiment; they will declare for the principle of relativity as fundamental and not as derived, just as Walther Ritz declared against electric and magnetic field-intensities E and H .

The author knows all this and covers most of it in different parts of his work, but seems nowhere to collect it. The brief discussion of the mass of light is too indefinite to convey any useful impression to me. The attempt at the end of the work to outline a further experiment bearing on the theory is laudable in itself and shows that the author has thought deeply into his subject from other sides than the logical.

EDWIN BIDWELL WILSON

MASSACHUSETTS INSTITUTE OF TECHNOLOGY

Osmotic Pressure. By ALEXANDER FINDLAY. Longmans, Green and Co., New York. Cloth, 8vo. Pp. 84. Price \$1.00.

This book by Dr. Findlay is one of the series of monographs on inorganic and physical chemistry of which he is the editor. The purpose of these monographs is "to place before advanced students of chemistry, accounts of certain sections of inorganic and physical chemistry fuller and more extended in scope than can be obtained in ordinary text-books." The present monograph deals with semi-permeable membranes and osmotic pressure, 6 pages; van't Hoff's theory of dilute solutions, 4 pages; direct determination of osmotic pressure of concentrated solutions, 12 pages; discussion of the recent determinations of osmotic pressure and of the van't Hoff theory, 4 pages; the general theory of ideal solutions, 10 pages; discussion of the osmotic pressure of aqueous solutions of cane sugar in the light of the theory of ideal solutions, 13 pages; indirect determinations of the osmotic pressure, 15 pages; views regarding the cause of osmosis

and the action of the semi-permeable membrane, 12 pages. Three pages are devoted to references. Two figures appear in the text. The treatment does not claim to be exhaustive "so far as concerns work important in its time but now only of historical interest," the aim being to give special attention to recent investigations.

The amount of space devoted to thermodynamical considerations and the so-called theory of "ideal" solutions, together with the mode of treatment and what one reads between the lines, clearly shows the author's leanings. It is, however, quite safe to say that those who have actually spent their time in the laboratory at practical work with innumerable solutions and diverse osmotic membranes, entertain very little hope of a better understanding of solutions and osmosis from thermodynamical computations and mathematical equations of what are termed "ideal solutions." One might indeed about as well talk of an ideal chemical compound, an ideal plant, or an ideal animal, as of an ideal solution.

The monograph will doubtless prove useful to students of the subject of osmosis, especially because of the references to the recent literature, even though these be incomplete. It moreover also contains a good, clear exposition of the existing physical theories of osmosis and solutions. But in a publication of this kind, which is especially intended for students, one has a right to expect something that will inspire and spur the student on to further experimental inquiry in the subject. In this respect, however, the monograph is sadly lacking, and how can it be otherwise, for to those that seek to solve the problem by thermodynamics and theories of "ideal solutions" new experiments along specific lines naturally do not suggest themselves, for they are really not required for the purpose of the explanation. A theory of "ideal solutions" suggests chiefly how known facts can be harmonized with it and how the "troublesome exceptions" may be accounted for; it does not suggest how new fields may be opened up. To those that thus vainly hope to solve the practical problems of solutions and osmosis particularly as they

relate to organic beings, one may well quote the immortal words of Goethe, "Grau teuer Freund ist alle Theorie und grün des Lebens goldener Baum."

LOUIS KAHLENBERG

THE BOTANICAL SOCIETY OF AMERICA

THE eighth annual meeting of the Botanical Society of America was held in the State Capitol Building, at Atlanta, Georgia, December 30, 1913, to January 1, 1914, about ninety members being present. The following officers were elected:

President—A. S. Hitchcock, U. S. Department of Agriculture.

Vice-president—B. M. Duggar, Missouri Botanical Garden.

Councilor—D. G. Fairchild, U. S. Department of Agriculture.

One hundred and thirty new members were elected to the society.

The report from the committee on the new journal was adopted. This provides for a co-operative arrangement with the Brooklyn Botanic Garden which will make possible the immediate publication of the journal and the first number of the *American Journal of Botany* will appear during January. All members of the society become contributing subscribers to the *Journal*, the price being fixed at \$3.00 annually to members and \$4.00 to non-members. Attention is called to the fact that candidates for membership (meaning those whose applications were received too late for action or those who may apply for membership during the year) may, upon approval of the council, receive the journal at the same rate as members.

The address of retiring President L. R. Jones on "Problems and Progress in Plant Pathology," together with the symposium on "Temperature Effects," participated in by Dr. Frederick Barry, Dr. B. M. Duggar, Dr. D. T. MacDougal and Dr. Forrest Shreve, will probably be published in the new journal of the society.

The dinner for all botanists was held New Year's night, the topic for discussion being the new journal.

Following are abstracts of the papers presented at the general sessions and at the newly organized physiological section:

The Seasonal Life History of Some Red Algae: I. F. LEWIS.

Experiments were performed at Woods Hole dur-

ing 1911, 1912 and 1913 on the following species: *Griffithsia Bornetiana*, *Dasya elegans* and *Polysiphonia violacea*. Tetraspores and carpospores were planted on oyster shells, which were then fastened to piles and left during the winter. The annual life cycle of the species studied runs as follows:

In June young plants become visible. These produce, for the most part, tetraspores, though an occasional sexual plant may be found. The tetraspores are released in July and germinate immediately to form the second crop, which consists of sexual individuals. These often occur on other algae and *Zostera*, whereas the first crop of tetrasporic individuals is confined to stones, piles and other objects of a more or less permanent nature. The sexual crop releases its carpospores in August or early September. It is the small sporelings from these spores which winter over. The individuals which have attained any considerable size all die at the approach of cold weather. The tiny holdfasts of the very young sporelings may be seen during the winter and spring. From them arise the tetrasporic plants of the first summer generation.

The alternation of generations in these species is thus connected with their seasonal occurrence. The sexual generation is characteristic of late summer, while the tetrasporic plants survive the winter and predominate in early summer.

There is no sharp line between the first and second crops, as a small percentage of both occur out of season. This is particularly true of the tetrasporic individuals, which under favorable conditions may survive throughout the summer and continue to produce spores up to September. A few of these belated tetraspores form holdfasts which winter over and produce the scarce sexual plants of the early summer following. In general, however, the two crops are well marked.

The Marine Algae of Peru: MARSHALL A. HOWE.

The specimens on which, chiefly, the paper was based were secured by Dr. Robert E. Coker, now of the U. S. Bureau of Fisheries, while acting as fishery expert for the government of Peru during the years 1907 and 1908. They are referable to about 100 species and they constitute one of the largest collections of algae thus far made in South America and by far the best ever brought from Peru. For the satisfactory determination of the specimens it has been necessary to examine the original materials of a considerable number of little-known and briefly described South American

species. The algae of Peru has been sparingly collected, especially during a period of seventy-five years preceding Dr. Coker's visit, and about one third of the species found by Dr. Coker appear to be undescribed. Although Peru lies wholly within the tropics, its marine flora, with the exception of a strip of coast about twenty miles long at the extreme north, is of a temperate rather than a tropical character. This is apparently due to the influence of the Humboldt or Peruvian Current, which brings northward the cold waters of the South Temperate and Antarctic regions. The mean summer temperature of the ocean at Callao, latitude 12° South, is said to correspond to that of New York, latitude 41° N., and of Monterey, California, latitude 36° N. Accordingly, one finds the typically tropical genera of green and red algae poorly or not at all represented on the coast of Peru. Instead, the larger brown algae, species of *Macrocystis*, *Lessonia* and *Eisenia*, are the dominating elements in the marine flora.

Lantern photographs were exhibited, showing some of the more characteristic species of the region. Among these were several illustrating the hapteres and the disposition of the sporangia in various forms of *Macrocystis*.

The Trend and Influence of Certain Phases of Taxonomy: AVEN NELSON.

Taxonomy has its place. It trains the perceptive faculties, teaches orderliness, develops judgment and strengthens reason. There is a saving grace in botany not found in most of the other sciences and this is exercised through taxonomy more fully than through all the other divisions of botany combined.

Systematic botany furnishes to the average layman a more continuous incentive for pleasurable and inspiring contact with the world about him than any other subject that lays claim to a place in a cultural course. It may be the primitive phase, but most great botanists at least began at this point, thus illustrating in their development the recapitulation theory.

Systematists were never so numerous nor more active than at present. All activity is not necessarily progress. Motion up and down may be spectacular and nothing more.

There is but one reason for the existence of the professional systematist; viz., to make it easier for others to know plants. If we fail in this one thing we fail in all. Judging by the indifference of the multitude to our work; by the hopelessness of the amateur who tries to acquaint himself with

the plants he meets; by the none-too-well concealed cynicism of our colleagues in other lines, we are failing in this. Our work has been analytic, not constructive. We have dismembered organisms and held up to view their component parts. We have been looking for differences, and with such amazing success that the fundamental resemblances have, for the most part, escaped our notice.

Morphology, physiology, ecology and economic botany in its scores of applications have all gone forward by leaps and bounds, but in spite of, not by the aid of, taxonomy. Not all taxonomic work has been useless or erroneous. Keenness of observation and great powers of discrimination are not lacking. It is not so much that what has been should not have been done, but rather that more should have been done to relate recent work to that which has gone before. Synthesis should have followed so closely upon the analysis of the elements of our flora that duplications would promptly have been discovered and the relation of each element to the other detected and stated.

We are on the eve of a new era of reconstruction. Already the pendulum is swinging back toward greater conservatism. The dismemberment of genera and the multiplication of species proceed more cautiously. This grows out of the revitalized aim, "make it easier for others to know plants."

Studies of Teratological Phenomena in Their Relation to Evolution and the Problems of Heredity: I. A Study of Certain Floral Abnormalities in Nicotiana and Its Bearing on Theories of Dominance: ORLAND E. WHITE.

Nicotiana plants showing petalody were selfed and progeny grown from them. In one race the abnormal character was extremely variable, some plants showing a large expression, other plants showing it only to a slight degree. This race varied in many other characters, proving the mother plant to have been very heterozygous. In another race, the abnormality was reproduced in all the progeny to the same degree as in the mother plant. With the exception of pollen color, no variation in other characters occurred in this race, indicating that it was largely homozygous in its hereditary constitution.

Pistillody originated as a discontinuous variation and was inherited in the same manner, crosses with the normal in one case giving in F_2 a progeny closely approximating a simple 3:1 ratio. In two hybrid F_1 families, it was completely recessive, while in what appears to be

another hybrid F_1 family, it is wholly dominant. The first two families differ from the last family in a large number of characters, as the ancestry of the latter involves another species.

The catacorolla race of *Nicotiana* originated through a discontinuous variation. When crossed with normal races, the F_1 progeny were either intermediate in character or absolutely normal, though the individual F_1 progeny from each cross showed no variation among themselves. Great variation existed between the different pollen parents of many of these F_1 individuals.

As a whole, the data secured from hybridizing races of normal plants with those possessing the three abnormalities discussed above support the view that dominance and recessiveness are not in any way attributes of the factor or "character" in itself, but are the result of the factor expression plus the modifying influence of the environment, whether genotypical (all the other genetic factors of the organism not primarily concerned in the transmission of a particular character) or external (soil, climate, etc.). The variability of the catacorolla expression in the 119 F_1 plants of ($-4-1A \times 119$ normals) is striking supporting evidence that this conception of dominance is the most tenable of those recently advanced by genetics.

Observations on the Behavior of Some Species on the Edges of their Ranges: ROBERT F. GRIGGS.

In the Sugar Grove region of central Ohio about 125 species, 13 per cent. of the native flora, reach their territorial limits. These plants are of diverse geographical affinity stretching away in every direction. More than half are abundant in many stations; only $\frac{1}{10}$ are rare; 21 are outliers far from their next station; 27 range continuously up to their limits; 77 reproduce well; only 18 reproduce poorly. The success of the seedlings in meeting plant competition is apparently more important than success of the reproductive apparatus. The theory that plants are confined to their optimum habitats at their termini does not accord with observation. On the contrary, some plants occupy the most unfavorable habitats, being forced by competition to grow where they can find room. The causes of the termination of these ranges is not evident. Climatic adaptability is evidently the limiting factor restricting the spread of species, but there does not appear to be such a climatic adjustment in the present instance, for most of these termini appear not to be stable, but are either advancing or retreating. There are tension zones between the different spe-

cies similar to the tension zones between ecological associations. By observation of these geographical tension zones it is possible to detect the trend of geographical movements. The indications at Sugar Grove are that Boreal types are giving way to others from the west and south. (To be published in the *Bulletin of the Torrey Botanical Club*, January, 1914.)

Variations in Iowa Oaks: B. SHIMEK.

Iowa occupies a peculiarly favorable position for the study of variations in oaks. Here northern, southern and eastern forms meet, and many of them appear in groves bordering the prairies.

Perhaps because of this, great variation is exhibited by many plants, those of the oaks being among the most striking and interesting.

The paper deals especially with variations in leaves and acorns, though other characters receive attention. Seventeen species and varieties are reported from the state, but chief emphasis is placed on variations in *Quercus macrocarpa*, *Q. alba*, the *Q. acuminata* group, *Q. rubra* and the *Q. coccinea* and *Q. velutina* group. The difficulty in determining species is considered and the value of specific characters is discussed, and special attention is given to the discussion of such disputed species as *Quercus coccinea*, *Q. ellipsoidalis*, *Q. boreale*, *Q. velutina*, *Q. texana* and *Q. Schneekii*.

The distribution of some of the species is discussed, and the record of the range of distribution of several species is corrected.

Segregation of Characters in First Generation Hybrids from Stable Species of Enothera: GEO. F. ATKINSON.

The parents are stable wild species of *Enothera* (*E. nutans* Atkinson & Bartlett, and *E. pyenocarpa* Atkinson & Bartlett),¹ found growing in the vicinity of Ithaca, N. Y. They have been cultivated through two generations. They differ in 25 to 30 clearly observable characters (a close analysis will reveal more) distributed in rosettes, stems, stem leaves, bracts, flowers, habit and propagation. Reciprocal crosses give rise to hybrids which show segregation of characters in the first generation. A number of the characters are contrast characters and behave as unit characters in segregation into twin and tripled first-generation hybrids.

Isomorphism in Capsella Hybrids: HENRI HUS.

In an earlier paper, presented at the Cleveland meeting, the presence of a gene *N*, to which the narrow character of the earlier leaves is due, was

¹ See *Rhodora*, 15: 83-85, 1913.

demonstrated for *Capsella Bursa pastoris* Setchell. This form was shown also to contain Shull's gene *B*, responsible for the deeply incised primary lobes, as well as for the presence of secondary lobes. At the time it was thought that in the *F*₁ generation of a plant of the partial zygotic constitution *BbNn*, the combination *BN* was not formed (gametic repulsion). Experiments carried on during 1913 have demonstrated that this combination does exist and also that, whenever a plant is homozygotic for *N*, the identical external appearance obtains, independent of whether the remainder of the ascertained zygotic constitution is *BB*, *Bb* or *bb*. Such combinations always yield the form *arachnoides*.

On Physiological Isolation in Types of the Genus Xanthium: CHARLES A. SHULL.

Remarkable variations in the burs of what has been considered *Xanthium canadense* Mill. have been noticed in Kentucky, in Kansas and elsewhere during the last several years. Three distinct types were selected in the fall of 1912 from the local flora where all were growing together on the same soil under identical conditions, for breeding experiments. These types have bred true to the parental generation, notwithstanding their close proximity in the field and their unguarded pollination. Differences were noticed in the burs, seeds, leaves, pigmentation, etc., and in the length of time required for the development of the reproductive organs. Because they bloom at different ages the types tend to remain distinct, although there is evidence that occasional hybrids may occur under natural conditions. The genus needs revision based upon experimental investigation.

On an Abnormality in the Flower of the Bellwort (Oakesia sessilifolia) which Prevents Seed Formation: A. F. BLAKESLEE and A. F. SCHULZE.

The abnormality consists in transformation of stigmas into anthers containing pollen grains which in sugar solutions germinate, as well as pollen from the normal stamens of the flower. Such abnormal flowers do not set seed.

Variability in a Vegetatively Pure Line of a Hermaproditic Mucor: A. F. BLAKESLEE.

Separation cultures from a single spore sowing of the mucor tested gave a small percentage of colonies sharply different from the stock form. The variations consisted in absence and increase or decrease of zygospore production, peculiarities in color, density and rapidity of mycelial growth, differences in height of mycelial filaments, the almost exclusive production of yeast-like cells in

place of a filamentous mycelium, the production of a filamentous mycelial growth devoid of sporangia, and a partial change at least toward the dioecious condition. Some of these variants are surely temporary conditions for they tend eventually to revert to the normal type. Others may be more permanent but have not been sufficiently investigated. All, however, tend partially at least to reproduce the new characters and some have for several sporangial generations kept their peculiarities in gross cultures during the few months it has been possible to propagate them. Many of them would undoubtedly be described as distinct species by specialists in the group.

The Development of Amanitopsis vaginata and Lepiota clypeolaria: GEO. F. ATKINSON.

Amanitopsis vaginata.—The primordium of the pileus arises in the middle of the upper part of the young carpophore as a dome-shaped area. This soon differentiates into an upper portion, the pileus primordium; and a lower one, the hymenophore primordium. By surface and marginal growth (the latter being epinastic) through the enveloping fundamental tissue, the pileus is formed. By downward and obliquely inward growth of the hymenophore through the fundamental tissue toward the stem fundament the primordial tissue of the lamellæ is formed. This gradually becomes differentiated into the primordia of the lamellæ, the trama of the gills being continuous with the trama of the pileus and the surface of the stem. There is no internal annular gill cavity as in *Agaricus*, *Lepiota*, etc. The fundamental tissue enveloping the primordia of pileus, hymenophore and stem is the "universal veil," or in fact gives rise to it at a quite late period in the organization of the pileus when an outer zone of the developing pileus changes into a gelatinous cleavage layer.

Lepiota clypeolaria.—Before any evidence of internal differentiation of the primordia of the pileus, hymenophore and stem, the young carpophore presents an outer duplex zone, the "universal veil" of Fries. The inner portion of this zone consists of a thin layer of subseuodoparenchymatous cells, the outer portion of long radially extending threads. After the origin of the stem and pileus fundaments, this "universal veil" is for some time separated from the pileus and stem by a zone of loose fundamental tissue. In the further differentiation of the pileus the surface threads grow through this intermediate zone of fundamental tissue and tie into the inner

zone of the "universal veil" so that the latter becomes "concrete with the surface of the pileus," no cleavage layer being formed.

A Preliminary Note on Spore-formation in Cyathus: GUY BISBY.

Practically no work has been done in recent years on this genus, making an examination of some interest. The nuclear divisions in the basidium is followed in *Cyathus vernicosus* by a nuclear division in the spore, making this species binucleated, whereas in *Cyathus stercoreus* the spores remain uninucleated. This cytological feature should be of advantage as a systematic criterion. Hyphæ growing from germinated spores have been observed, in forming anastomoses, to be met by a short protuberance from the hyphæ approached, apparently responding to some sort of attraction.

Variation in the Sporangia and Spores in the Saprolegniaceæ and its Bearing on their Classification: W. C. COKER.

Original observations on such variations are reported and the literature examined. It is concluded that while there is great variation in size, arrangement and behavior of both spores and sporangia, these (with possibly a single exception) are not of a character to confuse our present conception of genera in this family.

A Peculiar Water Mold: W. C. COKER.

A new species is reported from Chapel Hill, N. C., that exhibits in a confusing way certain of the reproductive peculiarities of *Achlya* and *Saprolegnia*. The spores on emerging swim away in part while others remain attached to the sporangium tip.

Occurrence and Periodicity of Water Molds at Chapel Hill, N. C.: W. C. COKER.

The results of about 450 collections are given, showing the relative abundance of the species found and their periodicity in so far as it exists. About 20 species are discussed.

Foliage Resistance of Different Varieties of Potatoes to Phytophthora infestans: I. E. MELHUS.

A study has been made of the varietal resistance of potatoes to *Phytophthora infestans* by artificially infecting the foliage. Varieties reputed to be either resistant or susceptible were grown in the greenhouse and subjected to favorable conditions for *Phytophthora* infection. The conidia of the fungus were germinated in water at optimum temperature conditions (about 13° C.). The resulting zoospore suspension was sprayed in the lower surface of the leaves of the healthy,

vigorous plants from 6 to 12 inches tall. Plants thus treated were held in a moist atmosphere at 20° to 25° C. over night and removed the following morning.

It is believed that by this method it is possible to learn the relative resistance of any variety without growing it under field conditions.

Plus and Minus Strains in the Genus Glomerella:
C. W. EDGERTON.

Cultures of *Glomerella* from different hosts have been obtained which show the presence of two different strains, these being provisionally called plus and minus strains. The plus strain produces normal perithecia in clumps or masses. The minus strain produces perithecia, usually immature, scattered profusely over the surface of the culture medium. When these two strains are placed in the same plate and allowed to grow together, a dense black ridge of normal perithecia develops on the boundary line. The two strains of one of these fungi have been carried for over three years and are still producing perithecia abundantly. That there is a fertilization between the two strains has been proven by isolating single asci from the boundary line between the two strains and allowing them to grow into colonies. These colonies usually produce both strains.

The Homology Between Spore-forms in the Ascomycetes: C. R. ORTON.

It has been pointed out in the rusts that there is a very striking morphological similarity between certain heteroecious species. This morphological likeness may be termed homology. It is pointed out in this paper that a similar homology exists between the conidial and asceigerous stages of certain Ascomycetes with respect to morphology of their spores. Examples are cited and discussed which show the likeness as well as the apparent exceptions. It is hoped that this fact may be of value to the mycologist and plant pathologist as a guide to life-history studies.

A Contribution to the Life History and Physiology of Cylindrosporium on Stone Fruits: B. B. HIGGINS.

A careful study of the life history of this parasite has brought to light a very interesting polymorphism. Four spore forms were found to be genetically connected in the life cycle as follows: Typical *Cylindrosporium conidia*, produced on delicate stromata in spring and summer; microconidia, produced on the same stromata in late fall; ascospores, produced in apothecia in the

dead leaves during the following spring; and apothecial conidia, produced later in the same apothecia following the discharge of the ascospores. All of these except the microconidia are capable of producing infection on the host plants.

A study of the morphological and biological characters of the organism from eight species of *Prunus* showed that the forms under consideration fall naturally into three species, one on each of three more or less distinct divisions of the host genus.

North American Species of Peridermium on Pine: J. C. ARTHUR and F. D. KERN.

The authors published a paper covering this ground in 1896, since which time much information has been added to previous knowledge, which the authors now propose to summarize. Some of the former names have been reduced to synonymy, chiefly as the result of culture work, and two new species are established, one from California and one from Guatemala. Some three or four species have been introduced from Europe, and are yet local. Doubtless the greatest economic interest centers about the cauliculous forms, native and foreign, and these have been discussed with considerable fulness.

Transpiration of Silphium laciniatum L.: L. A. GIDDINGS.

The experiments discussed in the present paper were carried on with *Silphium laciniatum* L. This plant was selected for experimental purposes because of the fact that it is a xerophyte growing in very dry exposed prairie regions and because, being taller than most of our native prairie plants, it offers opportunities for the study of normal transpiration in relation to evaporation at different altitudes above the surface of the soil.

The paper includes a discussion of the experiments carried on in the laboratory and in the field. A part of the experiments were carried on in the plant physiology laboratory of the State University of Iowa. The field experiments were carried on at the Macbride Lakeside Laboratory on West Lake Okoboji during the summer of 1912. Material for the study of the structure of the leaf was collected at the same time that the field experiments were being performed.

In the laboratory special attention was given to the effect of increased wind velocity on the rate of transpiration. Evaporation experiments were run with the transpiration experiments for comparison. In the field experiments attention was also given to the effect of wind velocity on

the rate of transpiration, but in these experiments relative humidity was also carefully studied and a comparison between the time of day when the lowest relative humidity occurred and the time of day when evaporation and transpiration were greatest. The rate of transpiration of leaves taken at different heights was studied, together with evaporation at the same heights.

The laboratory experiments showed that the rate of transpiration increased with wind velocity up to a certain limit, after which it did not increase in proportion to the increase in wind velocity. As a rule, in the field experiments transpiration was greatest before evaporation had reached a maximum.

The Effect of Certain Surface Films and Powders on the Rate of Transpiration: B. M. DUGGAR and J. S. COOLEY.

It is commonly observed that leaves of plants sprayed repeatedly with Bordeaux mixture may remain green and healthy, towards the close of the season, several weeks after unsprayed leaves free from fungous diseases have ripened. The experimental work reported up to this time has afforded no data indicating differences of sufficient magnitude between the activities and unsprayed leaves to account for the extended vegetative period. The experiments here reported were made for considerable periods of time with standardized castor bean leaves in potometers and with large numbers of potted tomato plants. Bordeaux mixture, aluminium mixture, lime, and certain other film-forming liquid and powders were employed. In every case the rate of transpiration was higher in the Bordeaux sprayed plants than in the controls, or as compared with the standard. The important differences make it necessary to give weight to increased transpiration in any explanation offered.

The Relation Between the Transpiration Stream and the Absorption of Salts: HEINRICH HASSELBRING.

During the winter of 1908-1909 experiments were conducted at Santiago de las Vegas, Cuba, in order to determine the comparative transpiration of tobacco plants under cheese-cloth shade and in the open ground. For this purpose plants were grown in galvanized iron tanks which were set into outer encasing tanks permanently sunk in the ground. Six tanks were placed among the plants of a field of tobacco grown under cheese-cloth, and six were set in an adjoining tobacco field not shaded. The quantity of water trans-

pired by the plants in the tanks was determined by daily weighings, the quantity transpired being replaced each day. At maturity the leaves, stems and roots of each plant were harvested separately, dried and ground. The ash was determined in water-free samples of the ground material. From the data the total ash of the plants was calculated.

The plants grown in the open absorbed about 28 per cent. more water than those grown under shade. The plants which absorbed and transpired the greater quantity of water contained both the smaller percentage and the smaller absolute quantity of ash.

It appears, therefore, that the absorption of salts by roots is independent of the absorption of water, and that the transpiration stream does not exert an accelerating effect on the entrance of salts.

Relation of Transpiration of White Pine Seedlings to Evaporation from Atmometers: G. P. BURNS.

An attempt was made to express the data recorded by meteorological instruments in terms of plant physiology and thus give them a botanical significance. The experiments were conducted in the state forest nursery under different degrees of "shade."

A comparison of the water loss from white and black atmometers with that from white pine seedlings under three conditions of shade used gave the following coefficient of transpiration:

Half shade	{ .0088 for black atmometer.
	{ .0087 for white atmometer.
No shade	{ .062 for black atmometer.
	{ .084 for white atmometer.
Full shade	{ .036 for black atmometer.
	{ .044 for white atmometer.

By use of these coefficients it is possible to calculate the water loss from white pine seedlings from the evaporation from the atmometers.

Half shade reduces the transpiration and the evaporation, but the graphs show that the response of the plants and the atmometers is not identical. The decrease in water loss due to "shade" for the first part of August, 1913, was as follows: black atmometer 50 per cent., white atmometer 44 per cent., white pine seedling 70 per cent.

Plants grown under the three conditions studied showed great variation in structure, in the amount of ash, and their chemical composition. The amount of water transpired by the no-shade plants was many times that transpired by the

plants in half and full shade, but the per cent. of ash, figured on a dry matter basis, is less in these plants than in either of the other two sets of plants.

Relative Transpiration in Rain-forest and Desert Plants: FORREST SHREVE.

Relative transpiration is defined as the ratio of the absolute transpiration of a unit area of leaf surface to the concurrent evaporation from a unit area of water. Its values give an index of the physiological controls of transpiration and of the action of light upon it. Relative transpiration and stomatal movement have been studied in several Jamaican rain-forest plants, with the general result that the two do not show a sufficiently close correlation to warrant the view that either is wholly controlled by the other.

A comparison of the rates of relative transpiration in rain-forest and desert plants shows them to be of the same order of magnitude in the two groups, as investigated under the conditions of their native environments, in Jamaica and in Arizona. Since the annual evaporation total in Arizona is ten times that in Jamaica, it follows that the absolute transpiration per unit area in plants of the desert is approximately ten times as great as it is in the rain-forest.

Seasonal Variations of the Osmotic Pressure of Pool, Pond and Stream Waters: EDGAR N. TRANSEAU.

Freezing-point determinations of the osmotic pressure of the natural waters of pools, ponds and small streams in central Illinois, made at intervals during the year 1913, have shown the following general results:

1. The osmotic pressure, expressed in millimeters of mercury, varied from 59 to 407.
2. The highest pressures were recorded during early spring when the water levels were highest.
3. The lowest records were made during the middle of September when the levels for the year were lowest.
4. Contrary to the statements often made, when the water level of ponds and pools lowers in late spring and summer, the osmotic pressure of the water is not increased, but is often greatly diminished.
5. When streams are reduced to pools, the water may have a higher pressure; as the pools dry up the pressure is diminished.
6. There are sudden and considerable variations in the pressure, sometimes coincident with weather changes, development or decay of algæ, etc., but

sometimes without apparent connection with other known factors.

The year 1913 was an exceptionally favorable one for testing the relation between lowering water levels and concentration, as there were no rains of consequence between the middle of April and the middle of September.

Zoospore Formation in Characium acuminatum: GILBERT MORGAN SMITH.

The mature plant is multinucleate and contains 16, 32 or 64 nuclei at the time that zoospore formation takes place. In the growth of the alga the nuclear divisions are mitotic and all nuclei divide simultaneously. There may be more than one pyrenoid present and the shape of the pyrenoid is quite irregular. Very thin starch plates are found around the pyrenoid, while other plates of stroma starch, probably derived from the pyrenoid, are found scattered throughout the cytoplasm.

The zoospores are formed by progressive cleavage. Cleavage takes place by a furrowing in of the plasma membrane. The first cleavage furrows are transverse and then longitudinal cleavage furrows cut the protoplasm into multinucleate masses. These multinucleate masses are then cut into angular uninucleate protoplasts by further cleavage. There is no division of the pyrenoid, but it remains unchanged till cleavage has been completed, when it disappears. The angular uninucleate protoplasts then become ovoid and a pyrenoid is formed *de novo* in each one. These are the zoospores which are liberated by the rupture of the old mother cell wall.

A Preliminary Report on the Isolation and Identification of the Enzymes of Fucus vesiculosus: B. M. DUGGAR AND A. R. DAVIS.

Peculiarities in the carbohydrate and nitrogen metabolism of the Fucaceæ make desirable a determination of the enzyme content of the growing tissues. Employing a variety of methods, no evidence has yet been found to indicate the presence of any of the commoner carbohydrases except cellulase. The commoner esterases are likewise absent, but amidases are well represented. Urea, especially, is rapidly transformed and urease is apparently widely distributed in the tissues. Oxidases have not been detected by any of the usual methods.

Relation of Certain Grass-Green Algæ to Elementary Nitrogen: JACOB R. SCHRAMM.

The number of species of algæ in which free nitrogen fixation has been investigated under pure cultural conditions is relatively small—represent-

ing not more than four or five genera. By a pure culture here is understood one containing a single species of alga free from all other organisms. What work has been done with pure cultures has led invariably to the conclusion that these forms are unable to fix free atmospheric nitrogen both in the presence of and absence of combined nitrogen and energy-furnishing materials. It is by no means certain, however, that forms do not exist which under one or all of these conditions are able to utilize elementary nitrogen. This thought is especially justified when the small number of free nitrogen-fixing species among the bacteria are considered.

By a variety of methods approximately 25 species were isolated in pure culture. Of these, two were blue-greens, 2 diatoms, and the remainder grass-greens. Seven species of the latter were tested for free nitrogen fixation in the complete absence of combined nitrogen. The effect of a slightly elevated temperature was determined in a duplicate series maintained at a temperature of from 29.5 to 30.5° C.

No fixation was observed in any of the species and, unlike certain fungi, no favorable effect was exercised by the higher temperature.

Indications Respecting the Source of Combined Nitrogen Used by Ulva lactuca: G. L. FOSTER.

Laboratory cultures of *Ulva lactuca* in seawater showed increased growth over that of the controls, when ammonium nitrate, urea or acetanide was added. Na-asparaginate did not increase the growth. Dimethylanilin and acetanilide were extremely toxic.

Parallel experiments in which the same compounds were added to artificial sea-water less nitrogen, gave similar results.

The Influence of Etherization on Certain Enzymatic Activities of Bulbs and Tubers: M. M. MCCOOL.

The experiments reported deal chiefly with the relative activity of diastases, oxidases and catalase in etherized and natural bulbs and tubers. Material from the two sources indicated differ materially in the activity of the enzymes. Diastatic action is greater in the etherized tissues; and this is also true for the action of oxidases and peroxidases. Catalase activity is, however, diminished by etherization.

On the Tracheary Origin of the Resin Tissue of the Conifers with Special Reference to Abies balsamea: R. B. THOMSON.

After a careful survey of the resin tissue in the

whole Conifer series, the conclusion has been reached that the ligneous resin tissue of the Conifers owes its origin to the modification of tracheary elements. This seems self-evident when it is considered that the Cordaitan forms, from which the Conifers are generally conceded to have arisen, have wood which is wholly tracheary. This view is directly opposed to that of Penhallow, who regards the resin tissue as derived from parenchyma, a view which is no doubt responsible for the recent theory of Kirsch that the vertical resin canals of the pines are proliferated from the parenchyma of the medullary rays.

In *Abies* Penhallow found transitions between the parenchymatous cells of the resin cysts and parenchyma-shaped tracheary elements. These he interpreted as evidence of the transformation of parenchyma into tracheary elements, whereas the writer presents evidence to show that both these and the parenchyma elements are derivatives of tracheids, the chief point being that these elements or combinations of them and the parenchymatous ones are in vertical series coterminous and in the same radial sequence with ordinary tracheids. They are thus derived from the same cambial cell which ordinarily gives rise to a tracheid. The modification occurs in association with the medullary rays, which are the only source of preservative in the most ancient fossil woods.

Cycad Pitting: H. B. SIFTON.

The pits on different parts of individual tracheids of the Cycads differ. The terminal ones, and those on the sides touching parenchyma tissue are more primitive than the others. In arrangement the pits are opposite or alternate indiscriminately, and are even quite commonly scattered or in small groups of two or three, facts which show that the arrangement of pits is not a feature of so great phylogenetic importance as has been thought. In cases of scattered or group pitting, there is present a probable precursor or primitive form of the "bars" or "rims" of Sanio, structures which have not been previously described in the Cycads, the only group of living Gymnosperms in which they have not been found.

A reexamination of type material of *Cordaites missouriense* (*C. illinoensis*) reveal several important features not mentioned in Penhallow's brief description.

The pitting is more primitive near the ends of the tracheids, and beside the medullary rays, than on other parts. This is shown by an increase in the number of rows of pits, and by the greater

dimensions of the pores. As many as six rows may be found where the tracheid touches the ray cell, and here the pores may extend considerably beyond the border of the pits. Again, in arrangement, the pits, though usually alternate, may be opposite, and are often scattered.

One remarkable feature is that many tracheids have bent ends, usually at the rays. These bent ends reach over several tracheids, and thus afford a means for radial conduction. Such tracheids have long been known in the Araucariaceae and are considered to be ancestral to true ray tracheids. They are for the first time described in a Cordaitan form.

Trabeculae are present in many tracheids; a feature which has not been noted previously among Cordaitan forms. Peculiar wandering parenchymatous cells are also found associated with the medullary rays.

Tyloses: A Study of Their Occurrence and Practical Significance in Some American Woods:
ELOISE GERRY.

In this study of the occurrence of tyloses in wood from trees of commercial size grown in the United States, 203 specimens were examined. The 143 specimens of hardwoods include 94 species belonging to 45 genera, 24 of which contained tyloses. The 60 specimens of conifers included 45 species belonging to 13 genera, 1 of which contained tyloses. Of the total 139 species examined, 56 belonging to 25 genera² contained tyloses.

Tyloses were found in the sapwood of all the species where their presence was established in the heartwood.

Well-developed tyloses were found in the outermost rings near the bark of 30 species of hardwoods.

True tyloses occur in the wood tracheids of certain pines, principally of the white pine group.

Epithelial cells sometimes effect a partial or even a complete tylose-like closing of the resin canals in *Pinus*, *Larix*, *Picea* and *Pseudotsuga*.

A considerable proportion of the vertical canals, even in the heartwood of the pines, are wholly or partly open.

Tyloses act like a natural filler in the hardwoods.

The woods where tyloses are abundant are, as a rule, durable.

² *Æsculus*, *Fagus*, *Liquidambar*, *Liriodendron*, *Magnolia*, *Oxydendrum*, *Platanus*, *Populus*, *Salix*, *Castanea*, *Catalpa*, *Celtis*, *Chilopsis*, *Eucalyptus*, *Fraxinus*, *Hicoria*, *Juglans*, *Morus*, *Quercus*, *Rhus*, *Robinia*, *Sassafras*, *Toxylon*, *Ulmus*, *Pinus*.

Tyloses, because they are very impermeable to air, water and creosote, reduce the penetrance of the woods in which they are strongly developed, thus decreasing, for instance, the tendency for such woods to become water-logged.

The presence of tyloses closing the vessels of a hardwood does not, however, prevent the penetrance of a preservative such as creosote into the other wood elements.

(To be concluded)

GEORGE T. MOORE,
Secretary

SOCIETIES AND ACADEMIES

THE TENNESSEE ACADEMY OF SCIENCE

THE annual meeting of the Tennessee Academy of Science was held in Furman Hall, Vanderbilt University, Nashville, Tenn., on November 28, 1913. President Watson Selva delivered an address relative to the aims and purposes of the Academy, and the following papers were read and discussed:

"A Natural Bridge of Tennessee in Process of Formation," by H. D. Miser.

"Physiographic Features of Tennessee," by L. C. Glenn.

"Development of the Phosphate Industry in Tennessee," by Lucius P. Brown.

"Caverns and Rock Shelters of the Cumberland Valley," by W. E. Myer.

"Food Preservation," by L. C. Bliss.

"A New Geological Map of Tennessee," by A. H. Purdue.

"Some Neglected Principles of Physiography," by A. H. Purdue.

"Some Early Topographic Maps," by L. C. Glenn.

The following officers were elected for the ensuing year:

President—L. C. Glenn, Vanderbilt University, Nashville.

Vice-president—W. E. Myer, Carthage.

Secretary—Roscoe Nunn, 1235 Stahlman Building, Nashville.

Treasurer—Archibald Belcher, Middle Tennessee Normal School, Murfreesboro.

Editor—James A. Lyon, Southwestern Presbyterian University, Clarksville.

The president appointed as members of the executive committee, S. M. Bain, University of Tennessee, Knoxville, and E. J. McCroskey, Lebanon.

ROSCOE NUNN,
Secretary

Gaede Molecular Air Pump

MADE BY E. LEYBOLD'S NACHFOLGER

Operates on a new and interesting principle, using no mercury. Will evacuate a 6 liter vessel from 10 mm. to .00001 mm. in 3 minutes. With its use, vapor may be pumped as well as gases, which is a very important feature.

Illustrated Descriptive Price list No. 6, fully describing this pump, will be sent free on request.

PHILADELPHIA

1913 THE RECORD YEAR OF THE U. S. BRANCH 1913

It is with a great deal of pride and personal satisfaction that we are looking back upon the year 1913. The new names of Institutions added to our ledgers are gratifying indeed, and we herewith express our thanks for the confidence they have bestowed upon us. The most reassuring fact, however, that we are on the right way of progress is the evidence we are receiving, that quality is the foundation of our success:

QUALITY OF MICROSCOPES and Lenses, as well as QUALITY OF SERVICE.

Dependable, reliable service is what we are striving to give.

Only one year ago we added a new wing to our works, accommodating four hundred more mechanics. Now we are building again. This is another sign of progress.

Incidentally striving to perfect our instruments, and always on the lookout for new methods to help solve the intricate problems confronting the scientists, no year has found us preparing to offer so many new things as the present.

Binocular vision microscope for oil immersion objectives

Diminutive microscopes for field work

Ball bearing fine adjustment. A reliable principle applied for the first time to the microscope.

The Base Sledge Microtome, 1914. The microtome of the future

Blood Counting Apparatus: Thoma-Metz for differential blood counting without calculation

New Epidiascope with Leitz Reflector, surpassing all in light power.

The heat is reduced to a minimum.

New Metallurgical Microscopes

Johannsen's Mineralogical Microscope

Simultaneous rotation of nicols and oculars in mineralogical microscopes

Berek's Mineralogical Demonstration Apparatus.

The above and many more will help corroborate our statement that we are trying to justify the confidence bestowed upon us.

ANNUAL SUBSCRIPTION, \$5.00

Eimer & Amend's Analytical Balance Model No. 2J

Capacity 100 grams in each pan. Sensibility $1/20$ mgr. \$60 net

¶ The design and construction of this balance are based on the most approved lines and represent the high skill of America's recognized foremost balance experts.

¶ The correct design and splendid durable construction of this balance recommend it both for routine industrial purposes as well as for the highest type of scientific work.

Space does not allow us to draw attention to all the splendid features of this balance; therefore, we mention its

Wide bows accommodating a 4-inch dish

Points of Superiority

¶ All flat planes, which reduces friction to a minimum, making the balance most constant in its weighings.

¶ Beam of hard rolled aluminium which is preferable to an alloy; blackened, with white graduations graduated on both sides of centre knife, for 5 mgr. rider (or 10 mgr. if desired).

¶ Rider arrangement of the most approved simple construction; it will not get stuck from infrequent use.

¶ Retains its sensibility under increased load.

¶ Case of French polished mahogany, seasoned and constructed in America. The door and drawer will not warp and stick.

Heredity and Eugenics

By John M. Coulter, William E. Castle, Edward M. East,
William L. Tower, and Charles B. Davenport

THIS book consists of a series of public lectures delivered at the University of Chicago. The lectures were given partly by members of the University Faculty, and partly by investigators from other institutions. As all these men are distinguished for work in these fields, the subject is summarized in an unusually authoritative way. The purpose of the volume is to present to the intelligent public an account of the more important and interesting movements in biology. It is profusely illustrated.

ASSUMING that one whom you may honor by election to this position of vice-president is expected to bring forward something concerning his special line of research, I have chosen the theme presented as my subject. It has been my lot to study more or less for the last forty years the relations of the Missouri River to the Pleistocene Ice.

This paper proposes to set forth some facts, some of them not widely known, with theories for their explanation, and to interweave the theories with sufficient speculation to form a consistent and not improbable story.

My personal examination covers only from the mouth of the Missouri to Bismarck, N. D., consequently I speak less intelligently of the region farther north.

The Missouri is not an old river geologically speaking. It has reached maturity over most of its course, but that is the result of the softness of the rocks over which it flows, rather than of the length of time it has occupied its present course. Nor is the degree of maturity proportionate to the softness of the rocks. For example, through the Dakotas it is in very early maturity, the flood plains are narrow and the trough is narrow and has steep sides, though the rocks are very soft, while in its lower course the breadth of its trough is quite strictly proportional to the softness of the rocks forming the bed of the present

¹ Address of the vice-president and chairman of Section E, Geology and Geography, American Association for the Advancement of Science, Atlanta, December 29, 1913.

stream. This indicates that the upper part of its present source is younger in time.²

The fact has long been recognized that the Ohio and Missouri rivers mark approximately the southern limit of the great ice sheet of the Pleistocene, as though the latter had exercised a controlling influence in the courses of the former. The Ohio, being

more accessible, has been studied by several geologists, but by none more carefully than by Professor W. G. Tight.³

There the general preglacial drainage was toward the northwest and was changed to the southwest. In the case before us we shall find reason to believe the preglacial

² Missouri Geol. Survey, Vol. X., Pl. XX., and U. S. G. S. Bull. 158, Pl. XXIII.

³ Professional Paper No. 13, U. S. G. S. (1903), "Drainage Modifications in Southeastern Ohio and Vicinity."

drainage was largely to the northeast and the ice changed it to the southeast.

The exceptional or anomalous course of the present Missouri is shown by the following facts. The Missouri at Ft. Stevenson, where it turns sharply to the southeast, is 1,720 feet A. T., while the Souris River, forty miles northeast, is 200 feet lower and from there is an open course to Hudson Bay, 900 miles away in a straight line. Instead of finding its way thither it reaches the Gulf of Mexico at just about twice that distance. To be sure other rivers show similar eccentricities, but they have mountain ranges to explain their action. Here there is nothing of that sort, but, on the contrary, only soft rocks lying horizontally. Moreover, the tendency for the Missouri to run at right angles to the direction of slope is shown further by the following facts: at Bismarck it is 220 feet higher than the James River at Jamestown, 105 miles east, and 400 feet above the Chyenne, 10 miles further east; at Pierre it is about 200 feet above the James, 105 miles east, and at Chamberlain 100 feet higher than the James near Mitchell, 66 miles east. At Sioux City the Missouri is 130 feet higher than the Des Moines at Ft. Dodge, 110 miles away, and at Council Bluffs 200 feet higher than the Des Moines, 115 miles east. At Kansas City it is about 300 feet higher than the Mississippi at Hannibal, about 200 miles east. This illustrates strikingly the tendency of the Missouri to follow the strike of the surface rather than the dip.

This anomaly is commonly ascribed to the influence of Pleistocene ice sheets. In general it is safe to suspect that the pre-glacial drainage of the region was toward the east or northeast. This agrees with the fact that streams along the line of the present Missouri trend eastward, except in the vicinity of glacial deposits, viz., from the

vicinity of Williston, N. D., to Kansas City, Missouri.

A. THE PROBABLE PRE-PLEISTOCENE DRAINAGE
ALONG THE LINE OF THE PRESENT
MISSOURI RIVER

The conclusions offered here should be valued carefully according to their weight. Some may be considered fairly established; others are given only provisionally. Moreover time permits us to indicate them only briefly without stating them so fully as might be desired. The main tributaries of the Missouri are from the west and have uniformly a persistently eastward direction. Furthermore, they may be grouped into clusters of two or three which converge as they approach the Missouri, and in several cases corresponding valleys are discoverable east of the Missouri. We will consider these groups in order.

1. *The Missouri and Little Missouri Rivers.*—The upper Missouri keeps a quite persistent easterly course from the mountains till it approaches the glacial drift near Nesson, N. D. The Yellowstone flowing northward joins it 40 miles west at Buford. The Little Missouri, with a course parallel to the latter, formerly joined the Missouri at Nesson, but now it leaves its old channel about 50 miles south of its old mouth, turns east and joins the present Missouri near Ft. Berthold. In view of these facts, probably the first suggestion which comes to mind is, that before the Pleistocene the Little Missouri joined the Missouri at Nesson and both continued their way eastward to the bend of Souris River and thereby reached Hudson Bay. This seems to agree with the fact that a terrace and old channel more than 100 feet higher than the present river leads eastward over a dozen miles into the morainic drift, but such a conclusion is forbidden by the discovery of a channel corresponding in height and size several

miles southeast leading across a large bend of the Missouri in a southeast direction. This seems to show quite clearly that the Missouri occupied this channel before the ice came. If this was true it is probable that the river continued south of east to Ft. Stevenson, where the present stream turns sharply southward. Knife River joins it several miles further south, and from the direction of the valleys and the fact that there is an unusually large valley for a small stream, Snake Creek, coming in from the northeast at Ft. Stevenson, it seems possible that the Knife and Missouri formerly joined near Ft. Stevenson and ran northeast to the Souris. The divide between is heavily covered with drift and we know nothing of the preglacial surface below, but some maps show a deep notch in the east front of the divide nearly north from Ft. Stevenson and in line with the northeast course of the Souris on the south side of its great bend. The height of the Missouri at Stevenson is close to 1,700 feet A. T.; of the Souris, 45 miles away, is about 1,500 A. T.; the height of the divide between, not less than 2,100 A. T. The altitude of the terrace at Ft. Stevenson is about 1,790, which would indicate that the old channel, if there, is filled at least 230 feet with drift, which is no uncommon thickness.

The Souris at present is several feet below the bottom of the drift there, and 50 to 75 feet below the level of the Souris plain of Lacustrine origin. The surprisingly low altitude of the Souris compared with that of the Missouri is most reasonably explained by great glacial erosion of the soft rocks underlying the region. The preglacial drainage doubtless had a much gentler slope than the present surface would indicate.

2. *The Heart and Cannon Ball Rivers.*—The Heart River joins the Missouri at Bis-

marck at 1,620 A. T. It shows a conspicuous terrace west of Mandan, which rises 110 feet higher. Southeast of Bismarck a terrace and broad valley-like depression runs up Apple Creek to Menoken, 15 miles east, then southeast as much further, to the southwest end of Long Lake. Its bottom fluctuates a little above and below 1,750 A. T. Cannon Ball River joins the Missouri about 30 miles south of Bismarck, opposite the mouth of Long Lake Creek, which drains a valley running north-northeast, in line with the lower course of Cannon Ball to the west end of Long Lake, and to the valley already mentioned as coming from Bismarck. Long Lake occupies a valley 25 to 30 miles long and 4 or 5 miles wide, continuing in the same direction, past Dawson, on the Northern Pacific railway, until it becomes filled with glacial deposits and untraceable. The altitude of the bottom of the valley near Dawson is 1,738 A. T. A lobe of the ice of the Wisconsin stage pushed up this valley as far west as Sterling. We have, therefore, quite convincing evidence that Heart and Cannon Ball rivers, at some time, most probably in preglacial times, flowed over the present divide between the Missouri and James rivers. Their course further east has been obliterated by the marked erosion and deposition of the various ice sheets, which have successively occupied the region further east.

3. *Grand and Moreau Rivers.*—The Grand River turns southeast before reaching the Missouri, apparently to go around the south end of a high ridge which lies just east of the latter stream. The Moreau probably joined it near this point not far from Mobridge. Both streams have several terraces along their valleys; those about 200 feet above the present stream are prominent and correspond to a broad valley which runs northeast 20 to 25 miles, where the surface becomes morainic and

rises gradually to the lowest point of the divide below the Missouri and James near Hillsview, at an altitude of 1,850 A. T. Thence is a gradual descent to the valley of the James near Aberdeen. That the axis of a lobe of ice lay along this line during the Wisconsin stage is shown by hills lying to the north and south, and these with the before mentioned ridge lying along the east side of the Missouri are all covered with morainic drift. It is not difficult to conceive that the preglacial Grand and Moreau, flowing 200 to 250 feet higher than now, went east to the James.

4. *Cheyenne and Bad Rivers*.—These constitute another pair which, probably uniting near Pierre, passed east to the James River Valley. The Cheyenne at that time lay further south in its lower course, as is indicated by broad high terraces. It passed south of Sully Buttes and eastward through the northern part of Hyde and Hand counties and the valley of Turtle Creek to the James near Redfield. Bad River may have joined it near the mouth of Okobojo Creek or may have followed the present course of the Missouri to the mouth of Medicine Knoll Creek and up its course to a junction in eastern Sully county. There is similar and clearer evidence of a former ice lobe here than that found in the last case, viz., the moraines to the north and south and along the east bluffs of the Missouri. The valley is so well marked that it is popularly known as the Ree Valley. The hills north and south rise to 2,000 A. T. The lowest part of the divide in the valley is 1,650 to 1,675 A. T. The depth of the glacial drift may reach 200 to 250 feet.

5. *White River*.—The course of this river is about as easily traceable east of the Missouri as that of Heart River, and for a similar reason, viz., because the ice did not quite reach to the Missouri in its valley. There are several prominent terraces along

White River, one 200 to 250 feet above the stream. At about the same level is a valley about two miles wide which runs from the mouth of that river northeast nearly 25 miles, where it is crossed by a moraine a little west of White Lake. White Lake may be considered in it and the depression continues down the Firesteel to the James, and then northward to join the Cheyenne. Red Lake occupies a portion of this same valley. Several miles south of White River is the old divide between it and Niobrara River. It stands out prominently as a high range of flat-topped buttes capped with Tertiary sandstone. The gorge of the Missouri through it is 750 feet deep. The preceding rivers after reaching the James Valley, which was then imperfectly developed, converged to a point northeast of Aberdeen, where there is a prominent gap in the highland east of the James, a little north of the south line of North Dakota. It is the wide valley of an intermittent stream called the Wild Rice River. That stream heads close to the James River and the divide between is not over 30 feet higher than the latter. The Wild Rice descends 300 feet in 60 miles and joins the Red River of the North.

We may conclude, therefore, that White River turned northward, joined the Cheyenne near Redfield and Grand River north of Aberdeen and met the Cannon Ball and Heart rivers coming from the north and all formed an important stream which found its way eventually to Hudson Bay, as Red River does to-day. It is possible that the two from the north may have found courses along the Cheyenne and not joined those from the south till later. No trace of the old courses could be found now, for the erosion of the Pleistocene must have lowered the surface scores of feet below the bottoms of the old valleys.

6. *Niobrara River*.—The valley of this

stream as late as just before the Wisconsin stage of the Pleistocene has been clearly traced from a little south of its present junction with the Missouri, northeast past Springfield and Tabor, to the James a few miles northeast of Yankton. There is little doubt that its preglacial course was the same so far. Its altitude was probably 100 to 150 feet above the present, *i. e.*, 1,300 to 1,350 A. T. It may have been 100 feet higher still. That it belonged to a different system from those hitherto considered is favored by the following facts: (1) there is trace of an old divide crossing the James River south of Mitchell. The Sioux Quartzite rises to more than 1,200 A. T. and Cretaceous rocks overlie to a height of more than 1,300. As this is in the center of the valley it is reasonable to think that 100 feet may have been carried away by glacial erosion. (2) There is a line of high ridges lying across the James valley north of the Niobrara, as though they were a remnant of a divide. I refer to the Choteau Creek Hills, James Ridge and Turkey Ridge. (3) The few traces of preglacial surface in eastern Nebraska and western Iowa seem to call for a lower drainage level than is indicated farther north, and also farther south. In short there seems to be need of finding a drainage outlet eastward to the Des Moines, or else to postulate a recently formed syncline for which we know no other evidence.

We conclude therefore that the Niobrara turned south and followed the courses of the James and Missouri to the vicinity of Onawa, Iowa, thence east and northeast through Ida and Sac counties past Wall Lake and thence southeast along the Racoon River.

This conclusion rests on a few apparently reliable reports from wells which show that the preglacial surface indicates a valley whose bottom is less than 900 A. T., in some cases less than 850. It has not been possi-

ble to outline the valley throughout, but half a dozen observations through Ida and Sac counties are most easily explained by such a theory. The fact that Wall lake lying on the summit formerly drained into Boyer River and now into the Racoon, and another fact that the Boyer rises east of the crest of the divide, has first a course east of south and at this point turns southwest, are also most easily explained by the theory given.

There was a descent of about 350 feet from Sioux City to Wall Lake.

7. Platte River of Nebraska.—This stream presents difficulties which have not yet been satisfactorily solved. The lowest surface overlain with glacial deposits in their original position seems to be about 970 feet A. T. in the vicinity of Omaha and Council Bluffs. The lowest striated rock surface is about 1,000 A. T., except a ledge at Omaha reported by Dr. C. A. White, which was about 6 feet above the river, and may have been the result of the action of river ice. It is conceivable that till may have slumped 30 feet into more recent excavations without clearly showing the fact. There are numerous evidences of such slumping elsewhere along the trough of the Missouri.

Now there seems to be quite clear evidence, as will be explained in the next section, that in early Pleistocene there was a divide at least 900 feet A. T. near Leavenworth and that south of it drainage levels were considerably higher than north of it. There would, therefore, have been insufficient slope in that direction to have excavated down to 970 feet A. T. 150 miles away. We seem driven therefore to find some other outlet.

Could it have been through to the Des Moines by the old channel in Sac county? That would have had a steeper grade than by Leavenworth. We have not been able

to find any other route to the Des Moines half as probable, but it has been argued elsewhere⁴ that eastern Iowa was formerly relatively considerably higher than now.

Could it have been southeast to the Grand River of Missouri? From the mouth of Platte River to a point in Grand River of equal altitude to the Missouri at Leavenworth is considerably shorter than to the latter point. It is quite possible that Grand River was not much higher in preglacial time than now. The region has not been examined with reference to this problem, but there is nothing in the course of present streams nor anything reported concerning the geology of that region which suggests that the Platte ever followed that course. We must therefore leave the problem not definitely solved, though the second hypothesis seems on the whole the more probable.

8. *Kansas River*.—The preglacial course of this stream is known to have followed nearly its present course but from 125 to 150 feet higher than now. This is shown by stretches of chert gravels with no admixture of northern erratics, such as the glaciers brought into the region. We may conceive that it followed the course of the Missouri from Kansas City to the vicinity of Miami and thence southeast by Salt Fork to the Lamine River and back to the Missouri again. If the Platte reached Grand River it would here have joined the Kansas.

From the distribution of the drift and loess in Missouri I argued some years ago⁵ that the Osage in early Pleistocene did not join the Gasconade but turned north by the present course of Auxvasse Creek and over into Salt River and so to the Mississippi. It does not seem very probable, though not clearly forbidden by known facts. The upland between rises to 870, and there is no

trace of divide between the Osage and the Gasconade, nor are they different in depth and age, as we should expect, if they had been separated till recently. The other alternative is to suppose that its course was down the present Missouri to its mouth, and that the shallow valley along the line of the Auxvasse and Salt Fork is due to general erosion acting on softer rocks, rather than to the presence of a master stream.

B. THE MISSOURI DURING THE NEBRASKAN STAGE

We now proceed to consider the probable history of the Missouri during the successive stages of the Ice Sheet of the Pleistocene. The stages usually recognized are in order: Nebraskan, Kansan, Illinoian, Iowan and Wisconsin, with substages of the last Altamont, Gary Antelope, etc., corresponding to the principal moraines left.

We know little of the Nebraskan Stage except that the ice did not then extend so far as the Kansan and that its deposits have been mostly carried away or hidden by the ice of the latter stage. The ice advancing from the north gradually pressed southward up the Red River valley, and dammed the master stream, formed of the streams we have enumerated as flowing northeast from the present James River valley, and caused an overflow into the Des Moines valley. Later it closed up their entrance into the Red River valley from the west, and caused the Missouri, Cannon Ball, Grand and Cheyenne to become a lake, and to overflow whatever divide separated them from White River, and eventually to overflow the divide separating them from the Niobrara, outlining for the first time the course of the James River.

Meanwhile, the ice passed more freely southward in the Des Moines valley, filling it and forcing the Niobrara to overflow what ever divide separated it from the

⁴ *Kan. Univ. Sci. Bull.*, Vol. VI., p. 375.

⁵ *Mo. Geol. Survey*, Vol. X., pp. 200 and 212.

Platte, and compelling all the streams mentioned to find their way around the edge of the ice southward, probably along the line of the present Missouri, or a little west of it, from Sioux City to Nebraska City and quite likely for a time through the Grand River of Missouri.

We are assured that the ice entered eastern Nebraska and reached to the south line of Iowa. In Dakota, it probably did not enter the James River valley extensively, for the gap by which it entered was probably narrow and its axis at right angles to the lobe which filled the Red River and Des Moines valleys.

C. THE MISSOURI DURING THE KANSAN STAGE

After a recession, we know not how far back, the ice advanced again to its maximum extent. The ice filled the Des Moines valley again, and overflowed southward to central Missouri, westward to Lincoln, Neb., and southwest to Topeka, Kan. As it crowded the great stream which skirted its edge, for the first time it overflowed the divide separating it from the Kansas, at Weston, Mo., a little north of Leavenworth. This fact is recorded in a stratum of boulders, nearly 20 feet thick and extending for miles along the bluffs east of the river. It rests on Carboniferous shales which rise about 140 feet above the present river. Among the boulders are scattering ones of northern origin attesting the vicinity of the ice sheet. Of course, when the ice reached Topeka, that locality of Weston was deeply buried with ice, and the master stream was forced much farther westward, as we shall see.

Meanwhile, the lobe entering the James River valley found, no doubt, a freer access because of the erosive work of the earlier ice lobe and of the streams attending it, for they worked on soft material. The latter must have been quite large, for they

drained the western edge of the ice quite extensively. Besides, the head of the ice behind was probably higher than before and the push forward stronger. Moreover, because of the latter condition, the ice overrode the divide to the north more, and the push was more southward than before, so that in this Kansan stage the Dakota ice lobe reached perhaps as far south and west as West Point, Neb., and became confluent with the west edge of the Minnesota-Des Moines lobe for hundreds of miles.

As the ice advanced in the James River valley the surrounding streams had to shift laterally westward and when dammed rose and overflowed local divides, working their way southward around the ice. The Missouri River entering the James River valley from the north, probably with the Souris, skirted the western edge of the ice, through the Dakotas to the Niobrara, being successively augmented by the various streams before mentioned from the west. Reaching the Niobrara it first followed it eastward to the vicinity of Sioux City, but later as the Dakota lobe crowded against the highlands of northeastern Nebraska, the river was choked off and, being dammed, it formed a deep lake, reaching far north along the western edge of the ice and eventually overflowed southward from the south bend of the Niobrara, past Creighton and Plainview, where the channel is still traceable, to the Elkhorn.

So also farther south, the stream was pushed westward by the advance of the Kansan ice from the former course along the east line of Nebraska, to a line along Logan, Elkhorn and Platte rivers, and possibly for a short time over the divide into the Nemaha to its earlier course through Missouri.

But eventually when the ice reached its maximum, the stream from the Niobrara before sketched crossed the line of the Elk-

horn at Norfolk, went up Taylor Creek, over the divide south at Creston, to the Platte, and over the divide south of that, near or east of David City, into the Big Blue. From there the course is clear.

The course from the Elkhorn to the Big Blue is largely conjectural. There may have been no distinct channel much of the way, for any considerable time. Drift deposits in Nebraska seem more than usually of a stratified or banded character especially toward the margin. There may have been extensive shallow lakes over much of the way.

Some present altitudes along this course will be instructive. Through the Dakotas, the altitude may have been 1,600 to 1,700 feet; Plainview is 1,683, Norfolk, on the Elkhorn, 1,525; Creston, 1,604; Schuyler on the Platte, 1,350; David City, 1,607; Miller-ton, on the Big Blue, 1,590. It may possibly have reached the Big Blue by Skull Creek and Oak Creek passing a little west of Lincoln and over the divide near Berks, without finding an altitude over 1,500 A. T.

After reaching the Big Blue the course was clear. The course was unobstructed to the Kansas at Manhattan, Kan., and eastward by the latter stream around the ice to the Mississippi. So at first, but as the ice continued southward it for a time dammed the Big Blue, a little below Blue Rapids, Kan., forming a short-lived lake which covered the eastern half of Washington county, Kan., and possibly at about the same time formed a similar lake, Kaw Lake as it has been called, in the valley of Kansas River, by filling the trough of that stream with ice from Wamego to Leocompton, a distance of more than sixty miles. Kaw Lake, soon filled and found an outlet over the divide south 200 feet higher than the present stream, and from the valley of one small tributary of the Kansas to another, till southeast of Topeka it reached the valley

of the Wakarusa, which conveyed it around to the valley of the Kansas below the barrier. At Kansas City the ice sheet crowded against the heavy limestone ledges in the northern part of the city, while the river occupied the valley in the southern part of the city, which leads eastward to the Missouri again.

This course was occupied through Kansas long enough to cut down quite a channel and to pave it with boulders and gravel, before the recession of the ice opened up the channel of the Kansas again.

D. WHILE THE KANSAN ICE WAS RECEDING

Though the ice sheet of the Kansan stage seems not to have paused in any one position long enough to form a marginal moraine anywhere, its advance and recession must have been very slow. After the Kansan resumed its preglacial course it cut down considerably before it ceased to receive the drainage of the ice, or before main drainage of the ice had shifted back to the line of the present Missouri, south of Dakota.

Omitting many details that might be given in the progress of shifting, I will simply give one which has been studied.

When the Kansan ice was at its maximum, the master stream of drainage flowed past Plainview at an altitude of 1,683. As the ice receded to the east and north the stream found a way at a lower level along the edge of the ice for several miles and then over the divide at Coleridge at 1,552, and then down Logan Creek. This allowed the rapid lowering of the water in the temporary lake in the Niobrara, and caused the deposition of much gravel along the line. As the ice receded farther the stream followed the ice front till it reached the line of the former course of the Niobrara, which passed northeast from its present

junction with the Missouri and joined the James several miles north of Yankton.⁶

At this point we may offer a word concerning the loess. This problematic deposit covers the Kansan till almost universally. The surface of the latter is generally much eroded, and because of this it has been argued that a long time elapsed between the deposition of the two formations. It was once claimed that the loess was largely of Iowan age, but it can be reasonably questioned whether erosion might not have been rapidly accomplished by the waters closely attending the edge of the ice, while the loess may have been deposited in flooded streams and local lakes remote from the edge. This silty material has doubtless been further modified by wind action and by later erosion and slumping. A strong objection to the flood theory, formerly felt, was the supposition that the channels of that time were as deep as the present, which we have seen was not the case. The drainage level of Kansan time was from 80 to 120 feet higher than that of the present, and it would have required scarcely a higher rise of water to have overflowed the uplands of that time than that which we shall find attended the retreat of the Wisconsin ice sheet.

E. FROM THE END OF THE KANSAN STAGE TO THE BEGINNING OF THE WISCONSIN

This was a long time during which the ice occupation of the region under consideration was not conspicuous. It corresponds to the Illinoian and Iowan advances and secessions of the ice. Elsewhere the ice found a growth into southern Illinois and far enough into southeastern Iowa to push the Mississippi westward nearly forty miles, then a recession and an advance from the northwest in eastern Iowa till the Missis-

sippi was pushed eastward over into Rock River.

Meanwhile the ice may have lingered in northern Minnesota and Dakota and have caused greater volume to the streams than now. The course of the master stream was doubtless in the James valley approximately along the course of the present James River, and further south along the present Missouri. Erosion deepened all channels, till their bottoms approached the level of the present surfaces of the streams. The valleys were widened considerably, particularly in the soft Cretaceous formations in the Dakotas and northwestern Iowa.

F. DURING THE ADVANCE OF THE WISCONSIN ICE

As in earlier stages the Minnesota and Dakota lobes of ice were the only ones advanced southward along the same lines which affected seriously the Missouri. They advanced southward along the same lines as before, and though probably with greater velocity and vigor, yet they did not attain so great extent. This may be explained possibly by a warmer climate than in former advances. The Minnesota lobe reached only to Des Moines, Iowa. The Dakota lobe only to the south line of South Dakota, although it pushed farther westward than before up the valleys of the western tributaries. Why this should be is not very evident. Possibly because of the greater depth and width of the trough of the Niobrara River where it was transverse to the paths of the ice, and because of the greater volume of water skirting the ice front there on the south. On the west, however, the greater maturity and therefore the greater width of the valleys of the western tributaries, like the White, Cheyenne and Grand, enabled the ice to push westward easier than before. At any rate the de-

⁶ *Bull. G. S. A.*, Vol. 23, pp. 463-470.

posits, moraines and till, show that the ice pushed westward up each of the valleys nearly to the line of the present Missouri. In other words, the ice filled the present James River valley so completely that all the western streams were dammed and the waters rose in each till an outlet was found southward. Between the Missouri and Cannon Ball and Grand rivers the divides were low and of soft material. But between the Grand and the Cheyenne was a prominent ridge capped with Fox Hills sandstone rising over 2,000 A. T. North of this was formed Lake Arikaree, reaching up the line of the present line of the Missouri to or beyond the mouth of the Yellowstone. Into it at several points the ice sheet at its maximum dropped small icebergs, by which boulders were scattered over the bed of the lake, and particularly on its southern margin, which is now in places marked by a line of boulder-capped buttes and ridges apparently corresponding to an old water level or lake margin.

The divide between the Cheyenne and White rivers was again comparatively low, but that between White and the Niobrara was again high, nearly 2,000 feet A. T., and capped with Tertiary sandstone. Through this an outlet was started which now is an imposing gorge, 750 feet deep. The ice also blocked the Niobrara from Springfield to Yankton, but did not force it over the divide southward as during the Kansan stage. Instead the river was crowded up on the south side of its valley where it excavated so deep a channel before the retirement of the ice that it became permanent.

So we have the present course of the Missouri from Ft. Stevenson to Yankton as a direct result of the Wisconsin stage of the ice sheet, as the course from Sioux City to Nebraska City was probably determined by the Nebraskan stage and from Nebraska

City to Kansas City and possibly to its mouth by the Kansan stage.

G. DURING THE RECESSION OF THE WISCONSIN STAGE

The Wisconsin was the last great invasion of the ice sheet, and its recession was long and marked by long pauses, when belts of knobs and ridges of debris were dropped from the nearly stationary edge of the ice. The first of these and the most voluminous was formed a few miles within the maximum extent of the ice. Before the next was formed there was recession far within the line of the second moraine and then an advance and a pause to form the second moraine. So that the Wisconsin stage had many substages similar to the stages already reviewed except that they were shorter and with ever-waning extent. During the recession from the first moraine there was the unloosing of great volumes of water as there was at the close of the Kansan, laden with much sediment, coarse and fine. The coarse dropped near the edge of the ice-formed valley trains, the fine, carried far, formed a deep accumulation of silt, particularly in broader and stiller portions of the streams. Such deep deposits are found well-preserved at many points. Their upper surface seems originally to have been nearly flat like a river terrace, but is now not only deeply eroded, but is more or less increased in height by the wash from the upland back. The lower limit is of course uneven, but usually is only a few feet above the present level of the streams. This deep silt and sand deposit is frequently from 80 to 120 feet deep. It closely resembles the loess often found on the uplands in the vicinity. In fact they have often been confused, nor is it any wonder.

This lower loess or early Wisconsin flood deposit is finely exposed at Kansas City,

Kan., also in the bench along the north side of Kansas City, Missouri. At Leavenworth, St. Joseph, and south part of Sioux City, besides several less conspicuous points between, and further down the river. Similar deposits are found in the lower part of the Kansas River near Edwardsville, Holli-day and Bonner Springs. Here it is due to back water from the Missouri, and the character and color differ from those of the Missouri River deposit.

After considerable examination I have no doubt that the similar terraces in western Iowa along the streams which headed near the edge of the Wisconsin ice are to be referred to the same cause. I refer to the terraces on the Boyer, Soldier and Maple. The absence of such along Mosquito, Nishnabotna and Nodaway confirms this conclusion. They were too far away to share in the floods from the Wisconsin ice.

Similar floods may have attended similar recessions from later moraines, but they were less effective, and after the third or fourth the ice retired too far away to affect the Missouri notably. Numerous lower terraces are found along the Missouri and its tributaries, which record such stages which attended the gradual deepening of their channels in the 15,000 or 60,000 years since.

In the recession of the ice, glacial lakes were formed from time to time. Lake Dakota was formed in the central part of the James River valley, while the fourth moraine was forming. It became nearly filled with a fine silt closely resembling loess.⁷ Later Lake Agassiz occupied the Red River valley, but it was beyond the scope of our subject.

I leave the subject with you. If I have made any point clearer or suggested a thought which may lead to further light I shall be well satisfied.

It may gratify our national pride a little

⁷ *Iowa Acad. Sci.*, Vol. XIII., p. 187.

to see how cleverly nature, not long ago, changed so much of the drainage which was sweeping the rich soil of our great plains into the British dominions, so that it was permanently diverted into our borders.

From this sketch, we see how nature has wrought the course and character of the greatest stream on earth, and one of the most important. It may not be called as historic as others, for its history is yet to come. Who can doubt that it is destined to be associated with some of the mightiest and most far-reaching events of the future,

J. E. TODD

UNIVERSITY OF KANSAS

BENJAMIN OSGOOD PEIRCE

THE death of Professor Benjamin Osgood Peirce at Cambridge on January 14 removes before his time one of the most valued members of the Harvard faculty and one of the most scholarly of American physicists. Having been asked by the editor of *SCIENCE* to contribute an obituary note, although feeling that one of his colleagues could do it in a more accurate manner, I could not forego the melancholy satisfaction of paying a personal tribute to the best of teachers and the cherished friend of thirty years. Peirce came to Harvard as instructor in the same year as the writer as a freshman, and the admiration he then inspired has only grown with years.

Peirce's first ancestor in America was Richard Norman, who came to Gloucester in 1623. His great-grandfather, Benjamin Peirce, was killed at Lexington. From him was also descended Benjamin Peirce, the distinguished mathematician. On his mother's side Peirce was descended from ship-owners in Salem. Born on February 11, 1854, at Beverly, it was from such sterling stock that Peirce inherited the New England conscience and capacity for thoroughness which were his leading characteristics. He received an excellent preliminary education in the schools of Beverly, and afterwards prepared himself for college, with plenty of Latin, Greek and mathe-

matics, then, as now the best training for a scientist, and he never forgot them. Neither did he slight the modern languages nor the vernacular, for nothing but the best of English ever proceeded from his mouth or pen.

Graduating at Harvard in 1876, he had already shown a marked talent for both mathematics and physics, and, receiving a traveling fellowship, he proceeded for further study to Leipzig, where he worked in Wiedemann's laboratory, and obtained the degree of Ph.D. in 1879. After this he spent another year at Berlin with Helmholtz, from whom he drew much inspiration. During these four years he had not only obtained skill in experimental research, but he had obtained a thorough grounding in the principles of mathematical physics, then almost entirely untaught in any American university.

Returning to the United States in 1880, Peirce spent a year in teaching at the Boston Latin school, and in 1881 received the appointment of instructor in mathematics at Harvard. This was not what he desired most, but he took hold of the work with enthusiasm, and among other subjects taught the calculus in a two-years' course, alternating with Professor Byerly. A splendid course it was, and those students who took it under one disputed with those taking it under the other as to which was the better teacher. But the most notable course instituted by Peirce and shared by this pair of masterly teachers was that one in which Peirce treated the theory of the Newtonian potential function, and Byerly the theory of Fourier's series. The writer well remembers his feeling of mystification, when at the end of his freshman year, on consulting the elective pamphlet to select courses for the next year, he came across the announcement, *Arbitrary Functions and the Theory of the Potential*. What on earth were arbitrary functions, and what was the "potential"? His highly respected teacher in the high school, hitherto an unflinching adviser, could not tell. But as a matter of fact this course marked a new era in American university work, for, as has been stated above, the teaching of mathematical physics in this country

was practically non-existent. I say this advisedly, having in mind that mechanics was taught to a certain extent, and that there were one or two courses on the theory of light, but the character of the teaching was totally different from that of the present era. Peirce had come back from Germany full of enthusiasm for the thoroughgoing German methods and the magnificent achievements of Gauss, Riemann and Dirichlet, which had opened up to him a new world. The backbone of theoretical physics is the subject of partial differential equations, and the most suitable gate to enter by is the theory of the potential belonging to forces acting according to the law of the inverse square. This Peirce had the insight to perceive, and made it his part to work up a course on this subject, which he treated with rare clearness and skill. The subject-matter of this course afterwards appeared in his treatise "*Elements of the Theory of the Newtonian Potential Function*," which passed through three or four editions and constituted a model of what such a work should be. One other of the fruits of his teaching was the short table of integrals, whose convenience has brought him the gratitude of many a student of the calculus.

In 1884 came the appointment as assistant professor of mathematics and physics, and Peirce took his place in the department of physics, to which he rightly belonged, and in which he was able to do his share in the reconstitution and modernization of that department which it was now to undergo in the new Jefferson laboratory. This was at the beginning of systematic laboratory work in physics in this country, and there was a certain amount of friction in getting the new ideas started. In 1888 with the retirement of Professor Joseph Lovering he was succeeded by Peirce in the Hollis professorship of mathematics and natural philosophy, a decided honor for so young a man. At the same time Professor John Trowbridge became director of the laboratory, and from this time on there was a rapid development of the laboratory work into what has become one of the best organized courses in the country, while re-

search was for the first time recognized and encouraged. Peirce took for his field the development of the laboratory course in electricity and magnetism, which he brought to a high degree of efficiency and interest. At the same time he devoted a large part of his powers to the graduate courses on mathematical physics, particularly the theory of electricity and magnetism and hydrodynamics. Besides this he threw himself vigorously into the prosecution of research, which he kept up with unabated assiduity until the end. Without going into these researches in detail, it will suffice to say that they were probably about fifty in number, and of considerable variety. Beside those on various subjects of mathematical physics, the experimental papers nearly all required an unusual amount of mathematical theory. Most notable are the researches on the thermal conductivity of various kinds of stone and its variation with temperature, in which he had the collaboration of his friend R. W. Willson, and his researches on magnetism, on which he was still engaged at the time of his death. Both these subjects are of extreme difficulty, and to them he devoted his best efforts, combining remarkable experimental skill with the mathematical knowledge necessary for their treatment. It was this rare combination that characterized the success of Peirce's work, and made him such a valuable colleague. It was said by one of his colleagues that he knew more physics than any other member of the department of physics, and more mathematics than any other member of the mathematical department, and the statement was not contradicted by any of them.

But this devotion to work, while producing most satisfactory results, was not without its penalty, for the inevitable result of overwork was a nervous breakdown, to which he was obliged to give way nearly a dozen years ago, and to take the much-needed year of rest in Europe. Unfortunately it was too late, and one year was not enough. Although he recovered sufficiently to resume his work, eventually at his normal pace, he really never recovered, and the rest of his life was a brave

fight against ill-health, carried on against tremendous odds, with a cheerfulness which deceived many. For years he suffered from insomnia, and at last the mechanism was entirely worn out, and after an extremely painful illness borne with great fortitude he succumbed to an attack of angina pectoris.

But it was not alone his scientific work that made Peirce such a source of strength to the university, it was the influence of his rare personality that drew to him hosts of friends among students and colleagues. Absolute self-abnegation and devotion to duty were the keynote of his character. With him modesty was so excessive as to almost cease to be a virtue. When consulted by a colleague with regard to some difficulty, almost invariably his first response was that he did not know anything about the subject, and it was necessary to draw him out with insistence in order to get at his superior knowledge. He was always fearful of giving trouble to some one, and frequently lay awake at night worrying over the troubles of others, never his own. Always cheerful and ready with a joke or anecdote, he was the kindest and sanest of advisers. Possessed of a sure and childlike religious faith, he was almost a Puritan in the conduct of his own life, but absolutely sympathetic and charitable toward others. Only himself he did not spare. Often his friends would remonstrate with him against his risking his health by overwork, but it was impossible to get him to desist. His teaching was characterized by the greatest clearness and infinite pains. Everything that he did was done with elegance and neatness. Often the writer has marveled to see the beautiful drawings that he made to illustrate his papers, the curves being laboriously cut out in zinc for greater accuracy. He kept a font of mathematical type in the laboratory, and set up many of the complicated formulæ in his table of integrals with his own hand. Though a thorough Yankee, he had a broad knowledge of Europe, spending much time in England and Scotland, and never forgetting his precious years in Germany. He was a great reader, and was extremely well informed

on a wide range of subjects, never giving up his interest in the classics. In every way Peirce was a living example of that breadth of character and interest which has so often been characteristic of great scientists, but which the specialist is so commonly supposed to lack.

Peirce's scientific activity was rewarded with many distinctions. In 1906 he was elected a member of the National Academy of Sciences. He was also a fellow of the American Academy of Arts and Sciences and of the American Philosophical Society, member of the American Mathematical and American Physical Societies, of the Astronomical and Astrophysical Society of America, the Société Française de Physique, and the Circolo Matematico di Palermo. He was one of the founders of the American Physical Society, and was last year elected its president. The election would have been renewed this year, but just before the meeting Peirce, evidently feeling his inability to discharge the duties of the office, had a notice sent out urging members not to vote for him. Unfortunately his misgivings were justified. In 1910 Harvard conferred upon him the degree of Doctor of Science.

Professor Peirce married, on July 27, 1882, at Edinburgh, Scotland, Miss Isabella Turnbull Landreth, by whom, with two daughters, he is survived. At his funeral Appleton chapel was crowded with colleagues and students, but the number of friends who will never forget his influence is far greater than could be contained in any building.

ARTHUR GORDON WEBSTER

*THE BRYANT WALKER EXPEDITION, OF
THE UNIVERSITY OF MICHIGAN, TO
THE SANTA MARTA MOUNTAINS,
COLOMBIA, IN THE SUM-
MER OF 1913*

THIS expedition, sent out from the museum of zoology, was organized to do zoological work in and about the west end of the Sierra Nevada de Santa Marta, in northeastern Colombia. The plan of the work was that adopted for all expeditions sent by the museum to

regions outside of the state of Michigan. Relatively small areas where a variety of conditions prevailed were located, and these were examined for those groups of animals to which the members of the museum staff are giving most attention. Particular study was made of the habits and local distribution of the species, and the results were preserved as specimens, notes and photographs of specimens and environments.

The party consisted of A. S. Pearse, of the University of Wisconsin, F. M. Gaige, of the University of Michigan, and the writer (in charge); and the groups which received most attention were the reptiles, amphibians, ants, crustaceans and molluscs. The collections of these forms may be summarized as follows: reptiles and amphibians, about 1,000 specimens; ants, 603 lots; crustaceans, 140 lots; molluscs, 150 lots. Small collections of other groups were made by preserving such material as was discovered, the collecting being restricted to a few forms which could be secured in series without interfering with the regular work. The groups which received such attention are leeches, earthworms, myriapods, scorpions, beetles, the genus *Peripatus*, and fishes. The other material secured consists almost entirely of specimens of those forms needed for illustrative purposes or as additions to the synoptic collections in the museum.

The expedition reached Santa Marta on July 1 and at once proceeded to an elevation of 4,500 feet. From this point a strip of territory from 2,200 feet to 8,300 feet (the summit of San Lorenzo) was explored for twenty-six days. On July 27 the party moved to the plain and spent nine days in continuing the explored strip from 2,200 feet to the foot of the range. The remainder of the time until September 1 was given to the investigation of the lowlands in three places—about Santa Marta, at Fundacion and on the Salamanca coast near Cienaga.

Not a little of the success of the expedition is to be attributed to the assistance and hospitality of Mr. and Mrs. O. L. Flye and the members of their family, Mr. and Mrs. M. A. Carriker, Mr. William A. Trout, consular agent

at Santa Marta, and Mr. Robert Sargent, Americans residing near Santa Marta. Through their efforts the party was provided with splendid facilities for field work and received substantial assistance in gathering material. The Colombian government permitted the free entrance of the equipment.

The collections of the expedition are now being studied by a number of investigators, and the results will be published from time to time as the studies are completed.

ALEXANDER G. RUTHVEN

MUSEUM OF ZOOLOGY,
UNIVERSITY OF MICHIGAN

THE PRESIDENT OF THE UNIVERSITY OF ILLINOIS

A CORRESPONDENT at the University of Illinois asks us to print the following communication:

In order to ascertain whether or not a persistent rumor that he had not the support of the faculty, was true, President Edmund J. James, of the University of Illinois, submitted the matter to a referendum vote of those of the faculty elected for two years or longer. The result was overwhelmingly against the rumor—188 expressing confidence in the president as against four who voted in the negative. At a later meeting a vote of instructors and assistants—those holding positions of one year tenure—revealed an even greater degree of confidence, but one dissenting voice arising. The latter meeting was called on the initiative of the men themselves.

The procedure was unique in American universities. Indeed the American university system has been criticized to the effect that the president or head has the power of an autocrat. Autocratic power, all history shows, is unsafe in any man's hands, as it soon becomes too dear to his heart. Therefore when a man elected to the presidency of a great university voluntarily submits the question of his own efficiency to the vote—a secret ballot—of his force, the act has signal significance.

During the ten years that Dr. James has served as president the university has made phenomenal growth in revenue, equipment, faculty, attendance and general standing. The commonwealth has been liberal; trustees, members of the faculty, alumni and other friends of the university have cooperated heartily in bringing about this result. The presi-

dent felt, naturally, that he also had been a factor in this upbuilding, that unless this was so after ten years of persistent and laborious work, his presence in such an institution as its head was a mistake. As a consequence he submitted the following to a referendum vote of the faculty: "I want to know whether in your opinion my administration as president of the University of Illinois during the past ten years has been liberal and progressive, and has promoted the substantial development of the institution on broad and scholarly lines, and whether as president I have the regard and cooperation of the faculty. On this proposition I ask you to vote either yes or no."

The result on a secret ballot was, as stated above, 188 to 4, in favor of confidence in the president.

Previous to this endorsement by the faculty the Illini Club of Chicago, consisting of 1,000 graduates, had expressed to the president their most unqualified approval in a set of resolutions passed at its annual business meeting.

Following this the pastors of some nineteen churches in the twin cities of Urbana-Champaign, including the Y. M. C. A.'s, Methodists, Catholics, and practically all denominations represented in the cities, sent a special delegation bearing a series of signed resolutions to President James expressing their confidence in him and their pleasure in the many evidences of the university's progress.

Still later the Alumnae Association of Chicago addressed a letter to President James saying among other things. "It is the earnest hope and wish of every member that you continue to serve as president in the work which has made possible the constant growth, the increasing influence and the general development of the University of Illinois."

THE CARNEGIE INSTITUTION EXPOSITION TO TORRES STRAITS

THE expedition of the department of marine biology of the Carnegie Institution of Washington has returned from the region of Torres Straits where it visited the islands between New Guinea and Cape York, Australia, remaining for the greater part of the time upon Maer Island, one of the Murray Islands, on the outer edge of the Great Barrier Reef south of the Bligh Entrance.

In response to Ambassador Bryce's letters of introduction the Governor of Queensland and

of New Guinea received the members of the expedition with a courtesy and kindness which contributed materially to its success.

The expedition was under the leadership of Dr. Alfred G. Mayer, with whom were associated Dr. Hubert Lyman Clark, of Harvard, Dr. E. Newton Harvey, of Princeton, Frank A. Potts, of Cambridge University, Professor D. H. Tennent, of Bryn Mawr College, and Mr. E. M. Grosse, of Sydney, whose excellent colored drawings served to illustrate the living aspects of the echinoderms which were collected by Dr. Clark.

The expedition was well equipped with apparatus and provided with a naptha launch, Mr. John Mills, of the department of marine biology, being the engineer.

For littoral echinoderms there is probably no richer region in the world than that of the Murray Islands, lying as they do about 70 miles south of New Guinea and within 6 miles of the outer line of the Great Barrier Reef of Australia. At Maer Island alone Dr. Clark collected about 150 species of echinoderms, and about 100 of these were beautifully figured by Mr. Grosse. Clark also found that crinoids are more active than has been generally supposed, some species being able to swim actively through the water.

Professor Tennent succeeded in effecting a cross between a male crinoid and the echini, and at Badu Island he obtained abundant material upon echinoderm crosses for an extensive cytological study.

Dr. Harvey found a holothurian, certain living pigments of which change purple in alkalis and red in acids, and he was thus enabled to determine the relation between the rate of penetration and the degree of dissociation of electrolytes.

Mr. Potts conducted several interesting ecological studies upon the habits of crustacea, and Dr. Mayer made an intensive study of the coral reefs, discovering that temperature is a factor of primary importance in determining the growth of corals. Those corals which are most resistant to high temperatures are those which are best able to withstand being buried beneath the mud, and this suggests that high

temperature produces death by asphyxiation.

Certain coral beds at Thursday Island, Cape York, Australia, which were measured and photographed by Saville-Kent in 1890 were remeasured in 1913 and species of Porites and Symphyllia were found to have grown in diameter at an average rate of 1.8 to 1.98 inches per annum, or about 44 inches in 23 years.

The health of the members of the expedition was good throughout the period of their investigations, and some interesting papers may be expected to be published by the Carnegie Institution of Washington as a result of their studies.

SCIENTIFIC NOTES AND NEWS

DR. CHARLES RICHTER, professor of physiology at the University of Paris, has been elected a member of the section of medicine and surgery of the Paris Academy of Sciences to replace the late Dr. Lucas-Championnière.

PROFESSOR L. MANOUVRIER, Paris; Professor Karl von den Steinen, Berlin; Dr. Alfred P. Maudslay, London; his Excellency W. Radloff, St. Petersburg, and Professor Émile Cartailhac, Toulouse, have been elected to honorary membership in the American Anthropological Association.

DR. CARL HUGO KRONECKER, professor of physiology at Berne, celebrated his seventy-fifth birthday on January 27.

OFFICERS of the Cincinnati Research Society have been elected as follows: *President*, Dr. Oscar Berghausen; *Vice-president*, Dr. E. R. Remelin; *Secretary*, Dr. J. L. Tuechter; *Executive Committee*, Dr. H. McE. Knower and Dr. Charles Goosman.

THE Syracuse chapter of Sigma Xi has initiated as non-resident members: Dr. Robert S. Breed and Dr. Ulysses P. Hedrick, of the New York Agricultural Experiment Station, and Dr. William J. Miller, of Hamilton College.

PROFESSOR C. E. SHERMAN, of the civil engineering department of the Ohio State University, has undertaken a complete examination on the summit level of the Ohio canal through

Akron, with a view to determining the availability of its waters for steam, sanitary, water supply power, and such other purposes as may be found advisable.

DR. GEORG AULMANN, assistant in the Royal Zoological Museum at Berlin, has been called to the directorship of the Natural History Museum at Düsseldorf.

PROFESSOR H. T. BARNES, of McGill University, lectured before a general meeting of the New York Academy of Sciences on February 16, his subject being "The Physical Effects Produced by Icebergs in the North Atlantic."

THE Society for Biological Research of the University of Pittsburgh held its first open meeting of the year 1913-14, on January 29, at which time Dr. Ross G. Harrison, of Yale University, addressed the society on "The Life of Tissues Outside the Organism."

DR. JOSEPH JASTROW, professor of psychology in the University of Wisconsin, gave the opening convocation address at the University of Missouri on February 4, on "Theory and Practice."

DR. CHARLES SEDGWICK MINOT, of Harvard University, made one of the addresses at the thirty-second annual banquet of the faculty and students of McGill University.

THE next convocation orator at the University of Chicago will be Professor James Rowland Angell, head of the department of psychology and dean of the faculties of arts, literature and science in the university.

DR. WOLFGANG OSTWALD, of the University of Leipzig, has delivered at the University of Chicago a series of five lectures on the subject of "Colloidal Chemistry."

PROFESSOR VLADIMIR KARAPETOFF, of the electrical department of Cornell University, has returned from a trip to Washington, D. C., where he delivered four two-hour lectures before the engineer officers of the United States Army, Washington Barracks. The lectures were given on February 5, 6 and 7, and the subjects treated were "Alternating Currents," "Theory of Electrical Machinery," "Design of Electrical Machinery," and "The Funda-

mentals of the Magnetic Circuit." Lieutenant Atkisson, who is in charge of electrical and mechanical engineering, and his assistant, Lieutenant Lampert, are former students of Professor Karapetoff's at Cornell.

THE Mendelian Society of Vienna has celebrated the thirtieth anniversary of Mendel's death by opening a new institute devoted to research in heredity.

DR. ROSWELL PARK, professor of surgery at the University of Buffalo, a distinguished surgeon and scientific author, died suddenly on February 15, aged sixty-two years.

DR. ALBERT CHARLES LEWIS GOTTHILF GÜNTHER, late keeper of zoology in the British Museum (Natural History), distinguished for his contributions to zoology, especially for his work on fishes, died on February 1 at his residence at Kew Gardens, in his eighty-fourth year.

DR. EDUARD HUBER, professor of Indo-Chinese philology in the French School at Hanoi, has died at the age of thirty-four years, while engaged in an expedition to Cochin China.

DR. FRITZ JUMMERSBACH, professor of agriculture at Munich, has died at the age of fifty-six years.

DR. KARL ALBERT NEUFELD, of the University of Würzburg, assistant director of the food laboratory, has died at the age of forty-eight years.

THE U. S. Civil Service Commission announces an examination for technical assistants in malaria investigations to fill vacancies in this position in the Public Health Service, for duty in the field, at entrance salaries ranging from \$1,800 to \$2,200 a year. The duties of this position will be to conduct laboratory studies of malaria, to make surveys of malarial regions, and to advise in respect to the prevention of the disease. It is desired to secure persons thoroughly competent to make thick and thin blood smears, stain the same and identify the plasmodium of malaria in all its stages in such preparations.

THE U. S. Civil Service Commission also announces an examination for geologic aid and assistant geologist, for both men and wo-

men, on March 11-12, 1914, to fill vacancies as they may occur in these positions in the U. S. Geological Survey, at salaries ranging from \$60 a month when actually employed to \$1,500 a year.

COMPETITIVE examinations for the position of sanitary supervisor, New York State Department of Health, will be held in various cities throughout the state, on March 7, 1914. Open to men and women. Application blanks must be filed in the office of the civil service commission on or before March 2, 1914. The following conditions are prescribed for candidates: (1) They shall be physicians. (2) They shall when appointed be not less than twenty-eight nor more than sixty years of age. (3) They shall either (a) have served as a health officer of a city, town or village having a population of not less than 3,000 persons, for a period of at least four years; or (b) shall have received instruction approved by the Public Health Council, or a duly authorized committee thereof, in sanitary science, including five hours' instruction per week during the school year, in an educational institution, and shall have had at least two years' experience in public health work; or (c) shall have received a degree, certificate or diploma in public health granted after the completion of a course approved by the Public Health Council, in an educational institution, and at least one year's practical experience in public health work; or (d) shall have submitted proof satisfactory to the Public Health Council, or a duly authorized committee thereof, that they have actually engaged in some form of public health work for a period of at least two years. (4) They shall not be allowed to engage in the regular practise of medicine or in any other regular occupation or business; but they shall be at liberty to retain or accept other positions in public health work, such as local health officer, teaching public health and related subjects, or other kindred lines of work. The State Department of Health, however, retains the right to determine at any time whether the extent of such other work interferes with the proper performance of his duties as sanitary supervisor. The State De-

partment of Health has fixed the salaries of sanitary supervisors at \$4,000 per annum, each sanitary supervisor being required out of this sum to incur all expenditures for traveling expenses which may be necessary to enable him to efficiently perform his duties in all parts of his district.

A CONFERENCE will assemble in Rome on February 24 and subsequent days to consider the question of an international convention for the control of plant diseases and the regulation of the importation of plants. It is described as a phytopathological conference, and is to be held at the International Institute of Agriculture. About fifteen countries are expected to be represented. Invitations were issued by the French government rather more than a year ago to a conference of this kind in connection with the general assembly of the International Agricultural Institute. In view, however, of the small number of acceptances received in time to arrange the meeting, the conference was postponed for a year.

THE Vienna correspondent of the *Journal* of the American Medical Association reports that by the bequest of \$300,000 under the will of the late Professor Leegen, a former member of the Vienna medical faculty, the Academy of Sciences of Vienna has obtained means to erect a special institute for physiology. The idea is to devote the institute to scientific research solely; no beginners will be admitted, and the men working there will be appointed as whole-time officers, who may *not* devote their time to any other office—as teachers in universities or hospitals. Furthermore, the academy has obtained also the Vienna Biologic Institute, together with a handsome sum to keep it going, from its founders and present owners. From this institute emanated the biological discoveries by Drs. Kammerer and Pribram and now, in connection with the above-mentioned “Leegen institute,” experimental physiology on a large scale, for purely scientific purposes, will be possible in Vienna, apart from the research going on in the university laboratories.

THE January number of the *Brooklyn Botanic Garden Record* contains a prospectus of courses to be offered by the Botanic Garden during 1914. There are 29 different courses, ranging from children's gardens and nature study to research work in plant physiology, mycology and plant pathology and genetics, and including courses in introductory botany, seven courses in household botany and horticulture, a course for the training of teachers of children's gardens, comprising nine different sub-courses, extending from January to October, and advanced botanical courses in plant pathology, fresh water microbiology, cytology, experimental evolution and phytogeography. In addition to the regular courses of instruction, there are also announced four courses of public lectures, two for children and two for adults, together with a statement of ways in which the Botanic Garden is prepared to cooperate with local schools in their botan-

ical and nature study work. Classes in botany from high schools in Brooklyn are now using the equipment of the Botanic Garden, in some cases being taught at the Garden by their own teachers, and in other cases by members of the Garden staff, appointed especially for this work.

THE city of Columbus and the State University have cooperated in the Columbus Horticultural Society, which is one of the oldest organizations of its kind in the United States, having been organized in 1845. The regular annual meeting was held in the new archeological and historical museum on the university campus, December 27, 1913. Professor William R. Lazenby was reelected president; H. Warren Phelps, vice-president; L. M. Montgomery, secretary; W. C. Mills, treasurer. The society has invested funds amounting to \$6,000. It publishes a volume of its proceedings each year.

SOME of the acacias, a group of trees with a world-circling range, are so valuable as a source of tannin and timber, says the Department of Agriculture in a bulletin recently issued, that their commercial cultivation in certain portions of the United States may prove profitable. Aside from their value for tannin and lumber, they are well adapted to the reclamation of sandy and semi-desert lands, some species being able to thrive with only three inches of rainfall. There are about 450 species of acacias, 300 of which are Australian species and the rest scattered over the world, principally in Asia, Africa and America. Australian acacias were introduced into California at about the same time the eucalypts were, and like the latter, have thrived there. Like the eucalypts they are not resistant to frost. At the present time the chief commercial value of acacias, says the department, seems to be for tanbark, although the tanbark species have important by-products. All of the leading tanbark acacias come from Australia, where they are generally known as wattles, from the fact that they were originally used for weaving and wattling the walls of huts. Actual tannin contents of the three principal tanbark acacias, as shown by analyses at the

University of California, are from 24 to 48 per cent. Oak and chestnut, the woods principally used in this country, yield from eight to thirteen per cent. of tannin. Acacia timber is beautiful in grain and durable in contact with the ground. Even the smaller species have a value for tool handles, furniture and various other useful and ornamental objects. Some of the best species yield a hard, heavy, close-grain, tough timber comparable to walnut and rosewood. In addition to tannin and timber, many of the acacias produce valuable by-products. The widely known gum arabic is derived principally from the Arabic acacia, though also from a number of Asiatic and African desert species. Cutch, an astringent gum in constant demand, is another acacia product. Many other kinds of gums are yielded by different acacia species. The flowers of still another species, known as cassie, yield a perfume, the manufacture of which at Grasse, France, the center of the perfume industry, is very profitable.

WE learn from the London *Times* that the plans of the Austrian Antarctic expedition, which it is hoped will sail from Trieste in the early summer, were set forth at a meeting held at Vienna on January 15. The principal supporter of the project is Count Hans Wilczek, to whose energies the success of the Austrian expedition which discovered Franz Josef's Land 40 years ago was largely due. Financial help is also being provided by the Academy of Sciences and the Geographical Society, but so far only about half of the required sum of over 600,000 kronen (\$125,000) has been obtained. The leader of the expedition is Dr. Felix König, of Graz, who took part in the German Antarctic expedition. The ship which has been acquired is likewise that which was used in that expedition; her name, however, will be changed from *Deutschland* to *Oesterreich*. Dr. König, who is being assisted by the advice of Captain Amundsen, intends to sail from Trieste to Buenos Aires, and thence to South Georgia Island, where an intermediate station fitted with wireless telegraphic apparatus will be installed. By this means it is hoped to keep up communication

between the ship, which will also be fitted with wireless, and civilization. The base is to be made close to a bay found by the German expedition in the newly discovered barrier, where it is hoped that the ship will be able to winter. The principal work will be carried out by sledge journeys, which will be made in three directions, one to the south with the object of reaching Queen Maud Mountains, the second towards Grahamland in order to try to discover its continuation southwards, and the third in the direction of the Enderby quadrant. The expedition is expected to cover two years, but provisions are being taken for three. From remarks made at the meeting by Professor Nordenskiöld the object of the expedition appears to be to discover the relations of the eastern and western section of the Antarctic regions with one another.

UNIVERSITY AND EDUCATIONAL NEWS

MRS. RUSSELL SAGE has extended her offer to give \$100,000 for a new dining hall at Princeton University provided that the university raise \$400,000 for the purpose.

UNDER the will of Dr. Cumberland George Herndon, two scholarships, named after the testator's father the William A. Herndon scholarships, have been founded in the department of medicine of the University of Virginia. Candidates must be unable to defray the expense of their medical education and must signify their intention of entering the medical service of the army or navy. The scholarships provide for the necessary expenses of the student during the four years of his course and will yield approximately \$425-\$450 per annum.

By an agreement between the universities of St. Andrews and Bordeaux, Dr. T. Pettigrew Young, lecturer in French at St. Andrews, will proceed to Bordeaux to act as exchange professor for the month of May, while during the same period Professor Charles Cestre, of Bordeaux, will join the staff of St. Andrews University. Professor Cestre has also been commissioned by the French ministry of instruction to deliver a number of lectures on the French literature and language in various parts of Scotland and England.

A NUMBER of Herefordshire teachers came out on strike on January 31 owing to the refusal of the local education authority to establish a scale of salaries, whereby if a teacher's record is satisfactory his pay shall increase automatically until a maximum is reached. We learn from the London *Times* that the strikers include the head teachers of about 80 out of some 176 schools. In addition, there are schools where assistants and not the headmasters or mistresses are ceasing work. More resignations will fall due as the weeks pass, until at the end of March 117 head teachers out of 189 employed will be idle, and, including assistants, a total of 223. Before the teachers' threat to strike the average salary of headmasters was £111, against an average for all the British counties of £146 6s., and the average salary of head mistresses was £88 16s., against £100 8s. for the English counties. There were similar disproportions in the salaries of class teachers. The local education authority, admitting that the salaries paid in Herefordshire were low, increased the salaries of certain teachers in December last by amounts totalling £1,300 a year.

DR. ETHELBERG D. WARFIELD has resigned the presidency of Lafayette College.

DR. GEORGE E. BREWER has been appointed to the chair of surgery at the College of Physicians and Surgeons of Columbia University. Dr. Walter B. James has asked to be relieved from membership in the medical faculty. He will retain his professorship and continue to direct research students from time to time.

J. F. McCLENDON, of Cornell Medical College, New York City, has accepted a position in the department of physiology, University of Minnesota Medical School.

DR. WATSON MARSHALL has been appointed demonstrator in laryngology in the School of Medicine of the University of Pittsburgh.

DR. MARIENNE PLEHN, assistant in the biological laboratory at Munich, has been made professor. She is said to be the fifth woman to receive this title in German universities.

DR. AUGUST BRAUER, director of the zoological museum of the University of Berlin, has

been called to a professorship at Bonn, but it is expected that he will remain at Berlin.

DISCUSSION AND CORRESPONDENCE

THE CYTOLOGICAL TIME OF MUTATION IN TOBACCO

IN the issue of *SCIENCE* for January 2, 1914, there is described a mutation that occurred in a variety of the common tobacco which gives promise to become of great economic value. In the article referred to it was assumed that the germinal change must have occurred after fertilization because the aberrant plant bred true. Professor Castle has asked if parthenogenesis may not be as reasonable an interpretation of the phenomenon since parthenogenesis is known to occur in *Nicotiana tabacum*.

The possibility had naturally occurred to us. And since it is impossible to prove a negative the same alternative may be presented in discussing any Angiosperm variation. Mrs. Rose Haig Thomas has reported parthenogenesis in *Nicotiana* and her work has been confirmed by Bateson on one variety.

One may not deny their conclusions, but the theorem of logic used above holds here as well. While admitting the possibility that Mrs. Thomas has found strains of parthenogenetic *Nicotiana*, it is possible that her results were incorrectly interpreted. We have made numerous attempts to secure parthenogenetic seeds from various species of *Nicotiana* without success. Dr. E. M. East and Mr. R. Wellington made nearly one thousand such attempts with over 50 species and varieties of the genus, also without success. We think it reasonable to assume, therefore, that parthenogenesis in our strain of *Nicotiana* is extremely improbable.

WINTER COLORATION OF WEASELS

TO THE EDITOR OF *SCIENCE*: It is well known that throughout Canada, and in the northern parts of the United States, the weasels become white in winter, whereas in the southern, warmer parts of the country they do not do

so, but remain brown. I am anxious to trace the southern boundary of the region in which these animals make this change—become white. I should be grateful, therefore, if any naturalist, trapper, or other reader of this journal, who believes he lives near this sought-for southern boundary, would send me word upon a post-card, or by letter, whether the weasels in his locality turn completely white, or only partly so, or whether some turn and others do not; and also whether the change appears to him to depend upon the coming of snow—that is does its time vary with the comparative earliness or lateness of a season?

ERNEST INGERSOLL

364 WEST 121ST STREET,
NEW YORK CITY

SCIENTIFIC MEN AND PHONETIC SPELLING

TO THE EDITOR OF SCIENCE: Professor J. C. Arthur, of Purdue University, says in SCIENCE for October 10, 1913, p. 513:

He is a brave man who openly throws stones at another man's domicile, even if he justify the act as altruistic, knowing the proverbial danger incurred.

Professor Arthur thereupon bravely throws stones at Dr. Dabney, and now I wish to throw a few friendly stones at Professor Arthur, at Dr. Dabney and at most of the other eminent contributors to SCIENCE. True,

It is not the proper plan

For any scientific gent to whale his fellow man.

But throwing stones is not "whaling," and all scientific gents will agree that a mere philologist can not be himself a scientific gent according to the statute in that case made and provided.

Professor Arthur chides Dr. Dabney for using the phrase "fungus growth," though he would excuse the phrase if it were intended for "fungous growth," "with the *o* accidentally omitted." But suppose Dr. Dabney, like some other scientific men, for example Dr. Wilder, should spell the adjective *fungous* with the *o* intentionally omitted? Would that be a violation of "good English" or of "good grammar"? Many scientific men would say so. Other scientific men would not say so.

The point that I make is that many contributors to SCIENCE, in criticizing matters of language and grammar, ignore a much more important matter in the relation of science to language. Even the gentlemen who write long and interesting articles about nomenclature, and insist with vehemence on the retention of this or that name or spelling or misprint, because it happened so (surely a free and easy attitude in science), do not touch upon the vital point. Most of them, by their example, or by abstaining from utterance or action, are preventing the scientific discussion, and the scientific settlement, of important matters of language relating to science. That is, they will not consider or discuss, or help others to consider or discuss, in print, the scientific notation of the English language, or of other languages. By their conservatism, obscurantism, ignorance, indifference, apathy, hostility, fury, cynicism, geniality, orthodoxy, call it what you will (and it is some or all of these), they prevent the editors and readers of the journals of science from dealing with this important matter of science.

They may write to their journals about the pronunciation of this or that word, sometimes about the etymology of this or that word, but, usually what they write, or at least what is printed, is superficial, insufficient or inexact; in a word, unscientific.

The reason is, I suppose, that most of the orthodox men of science do not know anything, accurately, about the pronunciation of English words, or about the sounds of English, or about the sounds of any language. They do not know, and will not try to find out, what symbols they should or might use in order to indicate with accuracy the sounds they wish to indicate or to discuss. And even those who do know these things, and can use, with a pen, an adequate notation of sounds, can not present that notation in the pages of a scientific journal, unless by a special arrangement with a more or less reluctant editor or group of editors, or at an expense which the writer himself must meet. In short, the orthodox scientific men of the United States and of Great Britain are, in this

matter, either unscientific, or are prevented, by some of their orthodox leaders from being scientific, in what should be an elementary matter of science, namely the accurate ascertainment and the intelligible record of the sounds of the English language, and of the other languages used in science. They are thus hostile to the sciences of philology and phonetics; and some openly proclaim their hostility.

If any of your correspondents who may do me the honor to dissent from these views will attempt to state in *SCIENCE* (and I am sure that the editor would be willing to permit the experiment) the actual facts about the words which Professor Arthur mentioned, namely, *fungus*, *fungous*, and *fungoid* (or any other group of words offering like conditions); to state exactly, in print, the pronunciation which those words have or should have; to state exactly what is or what should be the plural of *fungus*; to state exactly the nature of the difference between *funguses* and *fungusses*; to state exactly the different pronunciations of *fungi*; to state also whether the word so spelled is Latin or English, and whether it is Latin or English in all its pronunciations, or in one—if any one will try to do this, and succeed in doing it without recourse to the abhorred science of philology, and the despised “fad” of phonetics, I should like to see the result.

Even in the much simpler matter of a modernized spelling of English, we find the scientific journals holding aloof from the scientific view, and clinging to an unscientific and medieval spelling, while, nevertheless, in their columns we find frequent jibes or jabs at other medieval superstitions, and at other popular errors.

Yet nearly one fourth of the men who are recorded in Dr. Cattell's biographic dictionary, “American Men of Science,” in the first edition, signed a card agreeing to use some simplified spellings, and thereby gave the idea the value of their approval. No doubt they still cherish the same sentiments. In fact, some of them cherish these sentiments so fondly that they are wholly unwilling to part with them, or to share them with the public.

So they wrap themselves in their intellectual integrity, put over that the cloak of scientific orthodoxy, and go about disguised as harmless men. And the directors of scientific societies and institutions sit and do likewise. Then they arise and print pretty things about science and progress.

And longer should I sing, but with a frown the editor, impatient, rises. Having thus laid myself open to a lapidation of my meter (which some scientific gents *will* spell “metre,” or die in the attempt), not to say of my orthographic orthodoxy, I blush and drop my sling—before I smile a sickly smile and curl up on the floor.

CHARLES P. G. SCOTT

SCIENTIFIC BOOKS

Gas Analysis. By L. M. DENNIS, Professor of Inorganic Chemistry in Cornell University. New York, The Macmillan Co., 1913. Pp. 434. Price \$2.10 net.

This book may perhaps be described as the American Hempel. It is based upon the translation of Hempel's last edition, but extensive additions have been made by the author. The reviewer has always considered the plan of publishing researches in a text-book open to question, even though this adds materially to the value of the book to the investigator. It would seem better to make them much more widely known by having the researches appear in a periodical.

It is fair to expect in a work of its size that it should be encyclopedic and that the latest work should be included. No mention however is made of Uehling's automatic apparatus for analyzing chimney gas; of the Sargent gas calorimeter; of Elliott's gas apparatus, which is probably the most widely used of any for illuminating gas; of Hinman-Jenkins's method for total sulphur; of Crafts's method for purifying mercury; of the excellent work of Burrell and others of the Bureau of Mines in analyzing mine gases; of the detection of carbonic oxide by birds and mice; of the absorption of hydrogen by palladium chloride; of the practical application of chimney-gas analysis and of the calculations involved.

It is difficult to see in a work devoted exclusively to gas analysis why nearly a chapter should have been given to the heating value of solid fuel; or why the practically obsolete Honigmann gas burette should be described; or why the method of Drehschmidt-Hempel for total sulphur—which is almost never used in this country—is included.

One can not help being struck by the way in which reference has been avoided to American apparatus, and to a lesser degree to American work in this field. For example, Fig. 26 is of a German wet gas meter with the information that it can be obtained from Elster of Berlin! This extreme conservatism or love for German apparatus leads the author still to use the form of sulphuric acid pipette (p. 247) which is slow and may give rise to inaccurate results; to employ the expensive and clumsy double absorption pipette (p. 57) which is difficult to fill and empty; to fasten the gas pipettes with plaster of Paris (p. 54) into their fixed iron supports, instead of using screw clamp holders or a wax that can be melted and a movable collar which allows pipettes of almost any dimensions to be employed; and finally to say (p. 85) that the rubber protecting bulbs for the Orsat pipettes are a "draw-back" or "rapidly deteriorate"—which those of German make certainly do; had he used those of good American manufacture he would have had no trouble. It was shown years ago how all these difficulties could be avoided and experience with hundreds of students has confirmed the methods then recommended.

In spite of these defects the book has many excellent features. Chapter XI., on the calculations involved in the combustion of gases, is especially good, as is also the treatment of ozone and carbonic oxide. The chapter on acetylene is very complete. Among new apparatus is mentioned the gas refractometer and rotameter, and also some gas absorption bottles; among new methods may be noticed the determination of hydrogen by colloidal palladium and of oxygen by sodium hyposulphite. The book is particularly valuable in research or to the experienced man.

A. H. GILL

Mechanism. By ROBERT MCARDLE KEOWN, B.S., Assistant Professor of Machine Design, University of Wisconsin.

Professor Keown has attempted in this book to give a brief treatment of the subject of mechanism in such a way as to furnish material for half a school year's work of six hours per week partly in the class room and partly in the drafting room. The book contains little that is new in the way of subject matter covered and there is much similarity to other and older text-books in the general method of handling certain parts of the subject. The order in which the various mechanisms are considered is radically different from that usually followed and impresses one at first as being rather questionable, although the author seems to have found it satisfactory in his own teaching.

Chapter I. gives the usual discussions and descriptions of motion, velocity, etc., most of which are well stated. The student is then plunged at once, in Chapters II. to V., into the consideration of link work with all its intricacies, so puzzling to the student whose imagination has not yet been trained sufficiently to enable him to readily grasp this rather difficult part of the work.

Chapter VI. presents a fairly thorough and clear treatment of the subject of cams and is particularly well illustrated with a large number of diagrams and pictorial drawings.

Chapters VII. and VIII. treat the subject of gearing both for parallel and non-parallel shafts. The treatment is clear, with considerable practical information and a number of good illustrations.

Very little attention is given to the important matter of trains of gears. A short chapter is devoted to connection by means of belts, chains, and ropes, and another short chapter to various mechanisms for giving intermittent motion. The book contains a large number of illustrations, many of which are exceptionally good. A number of problems are given at the end of each chapter, adapted both for class room work and for solution on the drawing board. These form a valuable part of the book.

W. H. JAMES

Elementary Machine Design. By WILLIAM C. MARSHALL, Assistant Professor of Machine Design in Sheffield Scientific School of Yale University.

This book is prepared for the use of students who have not studied mechanics or mechanism. It is in reality a book of information and instructions for a course in drawing various machine details. The course as outlined would give a student familiarity with many of the details of machine construction and considerable practise in drawing them. No attempt is made, however, to give training which would enable the student to look at a problem in machine design in a broad way and to attack it understandingly. It seems fair then to call it a book of information rather than a text-book either of machine design or machine drawing. It would be a valuable handbook for a draftsman who is already familiar with the principles and methods of machine design.

The first chapter consists of a discussion of machine drawing, general in some respects and minute in others. The other chapters treat of rivets and riveted joints, piping, screws and bolts, shafting and shaft couplings, stuffing boxes, bearings, journals, hangers, pistons and piston rods, connecting rods, pulleys, belting, gearing, valves. Under the head of "Useful Information" are a number of convenient tables, and similar tables are scattered through the book.

W. H. JAMES

Grundriss der Kristallographie. By DR. GORTLOB LINCK. Third Revised Edition. Jena, Verlag von Gustav Fischer. Pp. viii + 272. Figs. 631. Colored Plates, 3. Price 11.50 Marks.

The appearance of a third edition of this excellent text-book of crystallography only five years after the publication of the second edition is an indication that its author has succeeded in treating what is usually regarded as a dry subject in a way that has attracted many readers. A part of the popularity of the volume is due no doubt to the fact that crystallography is being studied abroad more and

more thoroughly by chemists and physicists since the spread of interest in physical chemistry. Unfortunately, in America the science has few followers, but in Germany and England it appears to be enjoying a renaissance. Crystallography no longer deals merely with the description of crystal forms and the calculation of crystal constants. In its modern phase it is more directly concerned with the relations that exist between the forms and properties of substances and the proper explanation of these relations. Crystallography is rapidly becoming a branch of physical chemistry. It is because the author has realized this tendency in the science and has given us a book that deals so fully with the fundamental conceptions of physical and chemical crystallography that his volume has been received with such universal favor.

Of the new edition, 96 pages are devoted to the discussion of crystal forms and the balance to the discussion of the physical and chemical properties of crystals. There is no difference in method of treatment in the second and third editions. There are 27 more figures and 18 more pages in the new edition, but these additions are simply expansions of a few of the topics treated in the earlier edition. The additional figures were introduced mainly to emphasize some of the statements concerning the mechanical and optical properties of crystals, and the additional pages are the result of a little more detailed discussion of their optical properties. Throughout the book, where necessary, the text has been changed to bring it up to date and a few paragraphs have been introduced to call attention to some of the recent new work on crystals. The new figures are all of the same high grade of excellency as those characterizing the second edition.

The new edition is unquestionably the handsomest, best proportioned, most concise and at the same time most comprehensive elementary text-book on crystallography in any language. It is readable because logical, and it is modern. Moreover, it is not burdened by the involved sentences and the otherwise atrocious style that characterize so many German science text-books.

W. S. BAYLEY

SCIENTIFIC JOURNALS AND ARTICLES

THE opening (January) number of volume 15 of the *Transactions of the American Mathematical Society* contains the following papers:

T. H. Gronwall: "On the degree of convergence of Laplace's series."

L. E. Dickson: "Linear associative algebras and abelian equations."

W. B. Fite: "Some theorems concerning groups whose orders are powers of a prime."

R. E. Root: "Limits in terms of order, with examples of limiting element not approachable by a sequence."

O. E. Glenn: "The symbolical theory of finite expansions."

B. H. Camp: "Lebesgue integrals containing a parameter, with applications."

J. L. Coolidge: "Congruences and complexes of circles."

The December number of the *Bulletin of the American Mathematical Society* contains: Report of the Madison Colloquium, by Arnold Dresden; Report of the Vienna meeting of the Deutsche Mathematiker-Vereinigung, by Virgil Snyder; "On binary modular groups and their invariants," by L. E. Dickson; "On some systems of collineation groups," by H. H. Mitchell; "On the sumability of Fourier's series," by T. H. Gronwall; "Note on Pierpont's Theory of Functions," by G. A. Bliss; Review of Reid's Theory of Algebraic Numbers, by E. B. Skinner; Review of the Festschrift Heinrich Martin Weber zu seinem siebenzigsten Geburtstag, by R. C. Archibald; "Shorter Notices": Murray's Plane Trigonometry and Tanner and Allen's Analytic Geometry, by C. B. Hennel; Müller's Gedenktagebuch für Mathematiker und Ebner's Technische Infinitesimalrechnung, by E. W. Ponzer; Webster's Dynamics of Particles and of Rigid, Elastic and Fluid Bodies, by W. R. Longley; "Notes"; and "New Publications."

THE January number of the *Bulletin* contains: Report of the October meeting of the society, by F. N. Cole; Report of the twenty-fourth regular meeting of the San Francisco Section, by Thomas Buck; Report of the seventh regular meeting of the Southwestern

Section, by O. D. Kellogg; "The infinite regions of various geometries," by Maxime Bôcher; "Shorter Notices": Auerbach and Rothe's Taschenbuch für Mathematiker und Physiker, by G. A. Miller; Sommer-Levy's Théorie des Nombres algébriques, by E. B. Skinner; Carslaw's Infinitesimal Calculus, by A. M. Kenyon; Young's Monographs of Modern Mathematics, by R. D. Carmichael; Hawkes's Higher Algebra, by J. E. Rowe; Evans's Teaching of High School Mathematics, by E. B. Lytle; Fischer's Koordinatensysteme, by E. J. Wilczynski; "Notes"; and "New Publications."

THE February number of the *Bulletin* contains: "Some theorems on the convergence of series," by R. D. Carmichael; "A translation principle connecting the invariant theory of line congruences with that of plane n -lines," by O. E. Glenn; "Some mathematical booklet series," by R. C. Archibald; "Mathematical models," by R. C. Archibald; Review of Darboux's Systèmes orthogonaux et Coordonnées curvilignes, by E. J. Wilczynski; Review of Church and Bartlett's Descriptive Geometry, Low's Practical Geometry and Graphics, Hauck's Darstellende Geometrie, and Müller's Darstellende Geometrie für technische Hochschulen, by Virgil Snyder; "Shorter Notices": Hensel's Zahlentheorie, by L. E. Dickson; Volterra's Equations intégrales et Equations intégral-différentielles, by Jacob Westlund; Kowalewski's Komplexe Veränderlichen und ihre Funktionen, by Arnold Dresden; Bachelier's Calcul des Probabilités, by H. L. Rietz; Einstein and Grossmann's Verallgemeinerte Relativitätstheorie, by E. B. Wilson; "Notes"; and "New Publications."

THE BOTANICAL SOCIETY OF AMERICA

The Anatomy of the Node as an Aid in the Classification of the Angiosperms: E. W. SINNOTT.

The node of vascular Cryptogams and Gymnosperms is recognized as a conservative region. Investigation shows that the nodal structure of Angiosperms, as well, is slow to change and is

therefore of value in classification. In the Conifers the foliar supply leaves only a single gap in the cylinder, but in the lower Angiosperms the several traces which supply every leaf come off from the stele some distance apart and each causes a gap of its own. The primitive number of foliar traces and corresponding gaps among Angiosperms seems to have been three. This is characteristic of the Amentiferæ, the simpler Ranales, the Urticales and the Rosales. It also persists in some of the higher orders, such as the Caprifoliaceæ and Compositæ. In other groups, this condition has been amplified into one with a large number of strands and gaps, as in the Magnoliaceæ, the Polygonales, the Araliales and the Monocotyledons. In still others the three gaps have become approximated and merged into one, as in the Centrosperma, Myrtales, Ericales, Ebenales and Tubifloræ. The great simplicity of these nodal characters and their uniformity throughout such large groups of plants make them of much value in determining broad lines of relationship.

Primitive Characters Recalled by the Chestnut-bark Disease and Other Stimuli: I. W. BAILEY and J. S. AMES.

Dicotyledonous leaves with entire margins predominate in tropical regions, but are comparatively infrequent in boreal and mountainous regions. Subtropical and tropical representatives of boreal families have commonly entire leaves. Deeply lobed, dentate or serrate leaves are characteristic of Fagales endemic in northern latitudes. Toward the tropics the margins of the leaves become progressively entire. It seems probable that all living representatives, at least, of the Fagales, are descendants of boreal or mountainous forms, since vestiges of lobes, dentations and serrations persist upon young vigorous plants of subtropical species. Furthermore, the boreal type of foliage is recalled in mature parts of these plants by the stimulating effects of very rapid vigorous growth and the irritating effects produced by the attacks of insects and fungi. A striking illustration of these phenomena is afforded by the common American chestnut, *Castanea dentata* Borkh. Foliage formed subsequent to severe infections of the chestnut-bark disease (*Endothia parasitica* Murrill) is typically oak-like, frequently resembling closely *Quercus rubra* L. The reversion is not confined, however, to external characters. For the wood formed by the diseased cambium possesses anatomical structures which are a characteristic feature of the genus *Quercus*.

The Archegonium of Sphagnum subsecundum:

GEORGE S. BRYAN.

Sphagnum subsecundum, where studied in the region near Chicago for the past two autumns, has been found to bear enormous numbers of sex organs. The archegonial and antheridial heads are not difficult to recognize, and may be easily distinguished from each other.

A careful study brings out the following facts, as a general statement, in regard to the development of the archegonium. Archegonia are found to occur terminally on short side branches which rise near the apex of the main stem. The apical cell of one of these branches becomes an archegonial primordium in which oblique walls appear. The cell above these walls produces the primary archegonium; while each lateral segment cut off by them forms a secondary archegonium. In the archegonium initial the first wall is transverse, and usually subsequent transverse apical divisions give rise to a filament of cells varying in number from four to six. In each cell of the filament secondary divisions occur. Finally the apical cell of the filament enlarges and oblique walls, followed by a transverse wall, cut out a cover cell and a central cell. The cover cell forms chiefly the cap of the archegonium, while the central cell on division produces a primary canal cell and a ventral cell. The primary neck canal cell gives rise to a veritable number of neck canal cells, frequently from six to eight. The ventral cell divides very late, forming the ventral canal cell and the egg. Usually just after this latter division the neck canal cells break down, but the ventral canal cell is persistent, rounding off and coming to lie in the venter near the egg, from which it may be distinguished by its slightly smaller size. Shortly before fertilization the ventral canal cell goes to pieces.

So-called abnormalities occur. Two eggs and two ventral canal cells occur occasionally, while in one case a large venter was found in which were ten such cells.

On the Structure and Relationships of Macroglossum: D. H. CAMPBELL.

Macroglossum Copeland is a genus of Marattiaceæ, founded upon a species, *M. Alida*, sent from Sarawak in Borneo. The writer collected it at two stations in February, 1913, and secured material of both sporophyte and gametophyte. Another species was found growing in the botanical gardens of Buitenzorg, under the name *Angiopteris Smithii* Raciborski. The origin of this lat-

ter plant is unknown, but it was probably brought from Borneo.

Macroglossum differs from *Angiopteris* in several important respects. It has simply pinnate leaves, much more like *Danaea* than *Angiopteris*. The sporangia, while distinct, are quite different from those of *Angiopteris*, and closely resemble those of *Archangiopteris*. The number of sporangia in the sorus is much greater than in *Angiopteris*, sometimes exceeding 60. The indusium is also much better developed than in *Angiopteris*. There are also some important anatomical differences in the leaf structure.

Macroglossum is a large fern, the leaves being about four meters in length. In habit it resembles a gigantic *Danaea*—and also suggests strongly some of the larger species of *Zamia*. The leaflets reach a length of over 50 centimeters.

The prothallia are very large, sometimes nearly three centimeters in length by two in breadth. They are monocious. The antheridia are very large, but otherwise much resemble those of *Angiopteris*, as do the archegonia. The embryo has a conspicuous suspensor.

Macroglossum undoubtedly belongs to the *Angiopteridaceae*, but its affinities are rather with *Archangiopteris* than with *Angiopteris*. Like *Archangiopteris* it suggests a distant relationship to *Danaea*.

Morphology of Thismia (Bagnisia) americana
n. sp.: NORMA E. PFEIFFER.

Among the *Burmanniaceae* the forms closely related to *Thismia americana* have been found up to date only in the southern hemisphere, mostly in the Malay Archipelago. The particular subdivision to which this *Thismia* shows affinities has been for the most part discovered in recent years. The finding of one in a region so remote from the home of its relatives as Chicago, augurs well for the possibility of other undiscovered forms. The reduced size and anatomy of this saprophytic form are noteworthy. The floral axis arises simultaneously with a secondary root from the main root. The structure of the flower is similar to that of other *Thismias* of the *Bagnisia* section. Floral development is somewhat similar to that in the *Orchidaceae*, to which resemblance in other features is evident. The characters are deemed sufficiently distinctive to warrant the establishment of a new species.

Some Observations on the Anatomy and Other Features of the Black Knot: ALBAN STEWART.

Enlargements, popularly known as "black

knots," are formed on the branches of *Prunus virginiana* L. and other species of cherries, by the attack of the fungus *Flowrightia morbosa* (Schw.) Saec. These knots may arise primarily through the infection of the branch by means of spores, or, secondarily, by the spreading of the fungus through the tissues from a knot already formed.

Normal wood of *P. virginiana* usually contains rays from one to four cells wide in cross section. As a result of the stimulating action of the fungus these rays may become much broader in infected tissue, simulating the structure of compound rays. The production of the usual elements of the xylem is greatly inhibited during the first season's growth of the knot, but there is a correspondingly great production of xylem parenchyma, which is almost absent from normal wood. By further increase in size of parenchyma cells the knot is greatly enlarged during the second season of its development. The cambium is pushed outward by this means, and with it are isolated groups of fibers and other xylem cells. There is also an abnormal growth of the ray tissue at about this time, which ruptures the cambium, opposite the rays, and pushes segments of it outward into the bark. By further division of these misplaced cambium cells, various xylem elements are produced in the bark very much out of their normal position. The segments of the cambium, which remain between the rays, retain their relative position throughout the subsequent development of the knot, and give rise to wedges of xylem each of which is subtended by a mass of phloem on the outside.

There is apparently no abnormal growth in the outer portion of the bark. It is sloughed off just before the conidia are produced.

Homologies of the Frond in Lemna: FREDERICK H. BLODGETT.

The plant body in *Lemna* has been considered by various authors as a leaf, a stem or a combination of these, but in most cases little morphological evidence is advanced for one or the other idea. The structure of the frond, especially during its early stages, is used as the basis of a discussion of the parts present. It is concluded that the frond represents a single leaf at the tip of a stem of one internode, at the tip of which a dichasial stem apex is located, and ventrally an adventitious root developed. The dichasial buds are protected by the sheath or pouch of the frond, which develops simultaneously with the buds, from the tissue immediately about the insertion of the buds upon the apical tissues, becoming congenitally

fused with the basal margin of the leaf and the lateral margin of the stem (stipe) just where this unites with the leaf.

The vertical restriction upon axial growth is found to limit the development of new parts to the horizontal plane, and successive outgrowths are produced as lateral developments rather than in a vertical succession as in normal erect stems. No new parts are found, but those present have undergone reduction as a result of adaptation to the floating habit.

Development of the Embryo and the Germination in Lemna perpusilla: FREDERICK H. BLODGETT.

The embryo of *Lemna* develops directly from the egg cell, all of which is involved in the formation of the embryonic tissues, a true suspensor not being differentiated. The plumule becomes folded against the hypocotyl so that its tip is just under the micropyle. In this position it is enclosed by the overgrowth from the base of the cotyledon, forming a sheath or pouch. At the base of the plumule a bud is developed, which is the first true frond, and this bears the first pair of buds characteristic of the dichasial branching of the plant. The anterior half of the embryo is the cotyledon, and acts as an haustorial organ during germination, and does not function otherwise. The plumule emerges from the sheath from a horizontal slit, thus lying from the first in the plane of the water surface. The germination of the seed is in general of the type of *Pistia*, differences being due to the greater degree of reduction in the case of *Lemna*, rather than inherent variations in method.

The Chemical Dynamics of Living Protoplasm: W. J. V. OSTERHOUT.

Van't Hoff's formulation of the laws of chemical dynamics has proved so stimulating to various fields of chemistry that it may be expected to be similarly useful if it can be applied to the activities of living protoplasm. The writer finds that by measuring the electrical resistance of living tissues it is possible to follow the progress of reactions in protoplasm in the same way that van't Hoff followed the progress of reactions *in vitro*. It therefore becomes possible to apply van't Hoff's methods and formulæ directly to protoplasm in its living and active condition. The following example will suffice to show how this may be accomplished.

The electrical resistance of living tissue of *Laminaria* was measured by a method which has been previously described. The tissue had in seawater a resistance of 980 ohms. On being placed

in NaCl .52M (which had the same conductivity as sea-water) the resistance fell after 10 minutes to 865 ohms and after 20 minutes to 745 ohms: it continued to fall rapidly and finally became stationary at 320 ohms. This represents the death-point. The total change produced by the NaCl was 980 — 320 = 660 ohms. In order to find out whether this change had been produced in such a way as to correspond to a known type of chemical reaction the amount of change was measured at brief intervals.

According to van't Hoff we can determine from such measurements whether one, two or more substances are taking part in the reaction. If only one substance takes part (or if two substances take part but only one of them changes its concentration noticeably) the reaction is said to be of the first order (monomolecular) and it proceeds according to the formula

$$k = \frac{1}{t} \log. \frac{a}{a-x},$$

in which t is the time which has elapsed between the beginning of the reaction and the taking of the measurement, x is the loss in resistance at the time t , a is the total amount of change in resistance when the reaction is completed and k is a constant (called the velocity constant) which indicates the speed of the reaction. If the reaction is of the first order (monomolecular) k should come out constant provided the temperature be kept constant during the reaction.

In this case a , which represents the total amount of change, is 980 — 320 = 660 ohms, while x represents the loss of resistance after 10, 20, 30 minutes, etc. The calculations show that k is nearly constant: the variations are no greater than are commonly found in measuring chemical reactions in the test-tube.

Since the effect of NaCl is within wide limits completely reversible, without production of injury, the conception of chemical dynamics here developed applies not only to reactions which produce death, but also to reactions which involve no injury and which form a normal part of the activity of the cell. This conclusion is fully confirmed by experiments with a variety of other substances.

A Contribution to the Theory of Antagonism: W. J. V. OSTERHOUT.

By means of electrical measurements of living tissues it is possible to predict which salts will antagonize each other when allowed to act upon these tissues.

Differential Permeability: W. J. V. OSTERHOUT.

Various kinds of surfaces in the cell, such as the outer "plasma membrane," the vacuole-wall, the nuclear wall, the surface of the chromatophore and the cell wall can be proved to differ greatly in their behavior with respect to permeability.

The term differential permeability may be suggested as an appropriate designation of these phenomena.

The Effect of Antagonistic or Balanced Solutions Containing Sodium Chloride together with One of the Chlorides of Calcium, Magnesium, Potassium, Strontium, Ammonium or Copper, upon the Growth of Corn Plants Rooted in an Artificial Soil: JOSEPH S. CALDWELL.

The primary purpose of the work was to determine in how far the use of a solid medium having known physical properties may modify the antagonistic relationships borne by sodium to each of the other ions named.

For each of the six pairs of salts, cultures were grown in finely divided quartz to which the salt mixtures were added, the optimum water content for the quartz being maintained constantly throughout the experiment. For each pair of salts, ten to twenty different concentrations were used, the lowest of such concentration as to totally inhibit development, the last so dilute as to be entirely without effect upon the plants. For each of these concentrations, a series of cultures consisting of twelve to sixteen mixtures of the two salts in proportions ranging from 60:1 to 1:60 was made, with check cultures in each of the pure salts. The complete series for any pair of salts, therefore, shows for each salt the range of inhibitory, toxic and stimulatory effects, for comparison with the effects of isosmotic mixtures in varying proportions with the opposing salt. In all cases, results are measured by comparison of the dry weights of roots and tops, taken separately, for cultures allowed to grow under controlled conditions for 30 days.

Antagonism between sodium and strontium manifests itself at all molecular ratios between Sr 1: Na 10 and Sr 1: Na 20, and in all concentrations between those just permitting measurable development and those too dilute to have discoverable effect, but manifests itself only through its effect upon root development.

The effect of additions of calcium to sodium is merely to decrease the characteristic physiological and morphological effects of sodium in a degree directly proportional to the amount added, but in

no case can these characteristic effects be made entirely to disappear. The effect of calcium is a dilution effect and not an antagonistic one.

In mixtures of copper and sodium, sodium serves merely to dilute the copper salt, decreasing the toxic or the stimulatory effect in direct proportion to the amount added, but in no case annulling the effects of the copper ion.

Additions of magnesium to sodium in any proportions or at any concentration is without effect upon the development of aerial parts. In highly toxic concentrations, mixtures in the ratio of Mg 2: Na 1 give somewhat better development of roots, while in all stimulatory concentrations the ratio 1:1 gives greatest dry weight for roots. Mixtures of sodium and potassium inhibit development of both roots and tops, in all inhibitory or toxic concentrations, to a markedly greater extent than do isosmotic solutions of the pure salts. In stimulatory concentrations, the pure salts permit greater and more normal development than do mixtures. Sodium in any proportion, even in concentrations at which it is markedly stimulatory, decreases the stimulatory effect of potassium.

For mixtures of sodium with ammonium, highly toxic concentrations permit slightly greater development when the two ions are present in the ratio 1:1. For all stimulatory concentrations, the stimulatory effect is decreased in mixtures, growth becoming better as the ratio of one ion to the other increases from 3:1 to 60:1.

Metabolic Changes in Potato Tubers During Sprouting: CHAS. O. APPLEMAN.

The following metabolic changes occurred during the early stages of sprouting: (1) Under constant storage temperature the starch was depleted, while the reducing sugars showed a slight increase. The above carbohydrate changes were more rapid in the stem end. (2) Both diastase and invertase activity of the glycerine extract quickly doubled; the increase was greater in both cases in the extract from the stem half. (3) Catalase showed a marked increase which was slightly greater in the juice from the seed end where it was more active before sprouting. (4) The nitrogen of monamino-acids and their amide derivatives increased, while the nitrogen of diamino-acids and other organic bases and the water-insoluble protein nitrogen decreased. The abundant water-soluble protein nitrogen in the tubers showed a very slight increase. (5) Organic extractive and lipid phosphorus increase at the expense of protein and inorganic phosphorus.

The increase in lipid phosphorus began earlier in the seed end and increased more rapidly in this end. The decrease in the inorganic phosphorus at the same stage of sprouting occurred in the seed end only. It is interesting to note that in many cases the metabolic activity was greater in the stem half, although the sprouts were all borne on the seed end.

Biochemical Study of After-ripening in the Potato Tuber: CHAS. O. APPLEMAN.

Under normal conditions potato tubers will not sprout for several weeks after harvest. During this rest period certain changes occur in the chemical or physical situation of the buds or their immediate environment, which are essential to the release of the growth processes. These changes will be spoken of as after-ripening, using the term in its broadest sense.

The tubers used in this investigation produce sprouts much earlier from the buds on the seed end. The tubers were therefore cut in half and the analyses made separately on the seed and stem halves with the view to better detect the chemical changes characteristic of after-ripening.

The carbohydrate transformations during the rest period are dependent entirely upon changing temperature. Active diastase is present at all stages of the rest period and shows no increase during natural after-ripening. Protein, lipid, organic extractive and inorganic phosphorus, calculated to per cent. of total phosphorus, each remain constant up to the time of sprouting. After-ripening does not involve proteolysis or other changes in the various nitrogen combinations.

Metabolic changes involving the above substances and some others studied, begin rather suddenly and are concurrent with sprouting. They are, therefore, not primary processes of after-ripening.

The Physiology of the Rest Period in Potato Tubers: CHAS. O. APPLEMAN.

The rest period of the potato tuber is not firmly fixed and hereditary, as it can be entirely eliminated by means which will effect a proper adjustment between the bud tissue and external agents.

The Nutritive Value of Glycocoll to Plants from Peat Soils: A. DACHNOWSKI and R. GORMLEY.

In this preliminary statement data are submitted which were obtained from experiments in the laboratory with a variety of wheat and with several bog plants, among them *Oxycoccus*, *Scheuchzeria* and *Juncus*. Aside from the nutritive inequalities of amino compounds, the attempt is made to determine the limiting concentrations of organic and

inorganic acids and how far fungal micorrhiza are of importance in any special absorptive powers of plants.

Twining of Plants as Related to Withdrawal of Light: F. C. NEWCOMBE.

Various plants when deprived of light lose, in the course of a few days, their power of circumnutation, and pursue a straight course, either orthotropic or plagiotropic. This loss of circumnutation is not a starvation phenomenon, but is due to a change in geotropic sensitiveness. When the plant is restored to the light, it regains, after several days, its twining ability.

Influence of Light on Infection of Certain Hosts by Powdery Mildews: GEORGE M. REED.

An attempt has been made to study the influence of various factors as water supply, temperature, mineral starvation, light, etc., upon infection of hosts by powdery mildews. The results here reported relate to the influence of light.

Seedlings of barley and wheat have been grown in the dark until the first leaf was about 2 to 3 centimeters long. The plants were then inoculated with the mildew from their respective hosts. Some of the plants inoculated were kept continuously in the dark; others were removed at once and placed in the light; at intervals of 24 hours other inoculated plants were taken from the dark and placed in the light. The general results were that no infection occurred if the plants were kept in the dark after inoculation. Upon their removal to the light, infection occurred in proportion to the degree to which the etiolated leaves turned green. In general the period of incubation was retarded proportionally to the time the plants were kept in the dark.

Another series of experiments was carried out, first growing the plants in the light and then, after inoculation, placing them in the dark, some immediately, others at intervals of 24 hours. In the case of the plants placed at once in the dark no infection occurred. Those, however, that were kept in the light for one or two days became infected. The period of the incubation of the fungus, however, was materially retarded. In general the effect of the absence of the light upon the mildew is considered to be an indirect one and has to do with the primary effect upon the development of chlorophyll in the host cell. The infection fails to occur in those cells which have not developed the chlorophyll. The mildew then is a strict parasite attacking cells which are not capable of carrying on their normal functions.

These results are quite different from those obtained by inoculating etiolated plants with saprophytic fungi. Under such conditions, in some cases at least, saprophytic fungi are able to develop on the living tissues.

Resistance of Certain Fern Prothallia to Extreme Desiccation: D. M. MOTTIER.

The prothallia of *Camptosorus rhizophyllus* and of other forms found on dry hillsides and on limestone cliffs have been subjected to conditions approximating prolonged drought in the natural environment and to conditions of extreme desiccation in the laboratory. The part the prothallia play in the ecological adaptation of these ferns is shown by their survival of the most extreme laboratory conditions and by their subsequent production of sporophytes. For example, prothallia of *Camptosorus* survive exposure to glycerine-dried air for a period of six weeks, and those of other genera even a more extended desiccation under similar and different conditions. A continuation of work published in the November number of the *Bull. Torr. Bot. Club*.

The Pyrenoid of Anthoceros: F. McALLISTER.

All of the cells of the gametophyte of *Anthoceros laevis* contain a single large chloroplast, each of which has near its center a pyrenoid. The pyrenoid is not a homogeneous, kernel-like structure, as is the case in the algae, but is a multiple structure made up of a dense group of from 25 to 300 disc- or spindle-shaped bodies. These bodies are protein according to the standard microchemical tests. During photosynthesis the outer bodies are transformed directly into rudimentary starch grains while new bodies seem to be formed in the interior of the mass by fission. The rudimentary starch grains increase in size as they are pushed toward the periphery of the chloroplast by younger starch grains.

In the embryonic tissue of the sporophyte the pyrenoid can not be identified, but as these cells are pushed upward scattered bodies seem to aggregate in the center of the chloroplast to form it. When fully formed it differs in no way from the pyrenoid of the gametophyte. In the sporogenous layer, however, no pyrenoids are visible and the abundant starch grains of the spore mother-cells and the spores seem to be formed much the same as in other Bryophytes.

Physical Factors in the Cleavage of Cænoctyes: R. A. HARPER.

In the Myxomycete *Didymium* we have the spores formed by progressive cleavage essentially as in

Fuligo and the sporanges of the Mucorinæ. The presence of a capillitium of radial fibers, however, apparently makes possible the manifestation of certain factors in the process of division which are not so easily recognizable in other cases. The first visible step in cleavage seems to consist in the extrusion of water from the protoplasm. This water collects to form from one to several vacuole-like bubbles on the capillitial threads. Further contraction and extrusion of water goes on till each capillitial thread comes to be enclosed by a watery sheath. Progressive cleavage by furrows now sets in from the surface of the spore sack and from the surface of these water sheaths around the capillitial threads. Ultimately we have uninucleate spores. The whole process seems to involve active extrusion of water, and if we conceive that the chemical constitution of the nuclei is such as to favor the retention of moisture in the cytoplasm immediately adjacent to them we should have a condition which would tend toward the orientation of the cleavage furrows in such a position as to lead ultimately to the production of uninucleated spore masses.

The Harmful Action of Distilled Water: R. H. TRUE.

It appears probable that the problem of injury by distilled water is not a simple one capable in all cases of a like explanation. In some cases, distilled water obtained from apparatus having copper surfaces exposed to contact with the water undoubtedly derives certain toxic properties from minute traces of copper. In other cases, doubtless, it is possible for other harmful impurities to find their way into the product, but after the action of all the impurities has been accounted for there still remains a residuum of harmful action due to no known type of impurity. This mode of harmful action seems to be most marked in water which shows the highest resistance to the passage of the electric current.

Samples of distilled water which show the highest resistance are in general more harmful to lupine roots than waters containing a large quantity of electrolytes. These same samples of water withdraw electrolytes from the tissues of the roots when they remain in the water. This leaching of electrolytes is shown to be the probable mechanism by means of which purer samples of distilled water exert their harmful action on the roots. This action has a physical osmotic component, but for the roots of *Lupinus albus*, this osmotic factor seems to be decidedly secondary

in importance, the primary cause of injury being the extraction of electrolytes and perhaps of other substances as well. This extraction by distilled water is regarded as but a special case of the general type of injury wrought on cells by unbalanced solutions whereby certain necessary constituents, undoubtedly in part inorganic, are dissociated from their proper attachments in the complicated chemical and physical mechanism of the living cell. The distilled water seems to withdraw material required for the maintenance of the efficient action of the protoplasmic limiting membranes, with the result that the permeability of the cells is increased, and a further dissociation of electrolytes from their points of combination in the proteids, and other chemical structures of the cell, ensues. These dissociated electrolytes escape from the cell and increase the conductivity of the distilled water. When a trace of calcium ions is present in the distilled water, this dissociating power of the distilled water over the proteids and other chemical mechanisms of the cells is largely developed, and the chemical integrity of the cells is protected in some way not known.

This report is preliminary in its nature and is to be followed at a future date by a further contribution reporting the results of work now under way.

Distilled Water in the Laboratory: R. H. TRUE.

With the discovery made by Nägeli and Loew that copper distilling apparatus may yield water containing traces of copper sufficient to render the water harmful for plant cultures, the use of glass distilling apparatus became general, and carefully distilled water obtained from glass came to receive the general confidence of biologists. While in the majority of cases this confidence is well placed, errors in the interpretation of results are likely to follow a failure to recognize and allow for certain chemical and physiological characteristics of so-called pure water. Aside from the difficulty of obtaining pure water, this substance having been prepared in a pure state but a few times and then by chemists and physicists, there is the further difficulty of maintaining it in a pure state, since it readily becomes charged with gaseous products of the air, and when exposed to the air of the laboratory is especially likely to assume harmful properties for plant cultures—a danger which may be minimized through taking precaution to exclude these impurities from contact with the water. Another source of almost unavoidable contamination is seen in the solubil-

ity of the usual glass containers, which, unless specially prepared for the purpose, give up to the water sufficient solids to steadily increase the electrical conductivity.

Since a minimum of impurities will be found even in the purest water obtainable for practical experimental purposes, the action of the dilute solution which goes under the name of distilled water comes up for consideration. It has been shown that "distilled water" is injurious to the roots of certain plants, and that this action is paralleled by, and probably due, in great measure, to, the leaching of constituents necessary to the maintenance of life activities.

When check cultures grown in distilled water are used as a standard of comparison and regarded as normal, great danger of serious error in interpreting the results of biological experiments arises, since the behavior of check cultures in distilled water can not safely be regarded as an expression of normal activity.

It appears that plant physiologists need in their work a normal physiological solution, this normal solution to be such a medium as will cause the least possible disturbance to the usual activities of the plant. While the difficulties introduced by the use of a normal physiological solution are many, and will necessitate great care not only in meeting different requirements of various types of plants, but also with respect to the purity of chemicals used, the insolubility of glassware, the quality of distilled water employed, etc., there seems to be little doubt that such physiologically approximate mixtures are likely to give results much more closely approaching physiological soundness than is possible with the use of distilled water.

GEORGE T. MOORE

JOINT ANNUAL MEETING OF AMERICAN
ANTHROPOLOGICAL ASSOCIATION
AND AMERICAN FOLK-LORE
SOCIETY

THE annual meeting of the American Anthropological Association was held in West Assembly Hall, American Museum of Natural History, New York City, December 29-31, 1913, in affiliation with the American Folk-Lore Society. The joint program was unusually long and more cosmopolitan than at any previous meeting, and the sessions were well attended. The thanks of the members of both societies are due to the American Museum

of Natural History for the ample and attractive facilities provided; to the Explorers' Club for the welcome extended to members of the Council, and to Mr. George G. Heye and Professor Saville for a private view of the Heye Museum.

At the Cleveland meeting the secretary was instructed to prepare a list of names of persons eminent in anthropology to be submitted with the view of election to honorary membership at the New York meeting of the association. Pursuant to his instructions the secretary submitted a list which was referred to a committee named by President Dixon: Boas (chairman), Hrdlička, Peabody and the secretary, with instructions to recommend five names. The report of this committee was approved and the following honorary members were elected by the council: Professor Léonce Manouvrier, Paris, France; Professor Karl von den Steinen, Berlin, Germany; Dr. Alfred P. Maudslayi, London, England; His Excellency W. Radloff, Saint Petersburg, Russia; Professor Emile Cartailhac, Toulouse, France.

Dr. Goldenweiser reported for the committee appointed to consider the advisability of devoting one number of the journals (*American Anthropologist* and *Journal of American Folk-Lore*) to recent progress in the field of American anthropology in connection with the International Congress of Americanists to be held in Washington, D. C., October 5-10, 1914. The report was accepted and Dr. Goldenweiser was instructed to complete his correspondence with contributors and to send the contributions to the editors for publication. The editor of the *Anthropologist* was instructed to have extra copies of the number in question printed for free distribution among foreign members of the International Congress of Americanists. The contributions already promised are: "Archæology," W. H. Holmes; "Physical Anthropology," A. Hrdlička; "Material Culture," Clark Wissler; "Mythology," Franz Boas; "Linguistics," P. E. Goddard; "Ceremonial Organization," R. H. Lowie; "Religion," Paul Radin; "Social and Political Organizations," A. A. Goldenweiser; "Historical Relations," J. R. Swanton and R. B. Dixon.

Dr. Hrdlička gave a detailed report of the progress made by the local committee in preparation for the forthcoming International Congress of Americanists to be held in Washington, D. C. The American Anthropological Association accepted an invitation to become a member of the congress, to which President Dixon named Franz Boas, of

Columbia University, and George Grant MacCurdy, of Yale University, as delegates from the association.

A letter was read from Professor A. L. Kroeber, who expressed the hope that the association would accept the invitation of Mr. James A. Barr, manager of the Bureau of Conventions and Societies of the Panama-Pacific International Exposition, to hold a special session in San Francisco during the exposition. Professor Kroeber announced his readiness to do everything in his power to help make such a meeting a success. The invitation was referred to the executive committee with power to act.

The selection of a place for the next annual meeting of the association was likewise left to the executive committee, which has decided that the meeting shall be held in Philadelphia during the Christmas holidays, in affiliation with Section H of the American Association for the Advancement of Science.

The chair appointed a committee on nominations consisting of Boas, Lowie, Swanton, Gordon and MacCurdy, whose report was accepted by the association, the election of officers resulting as follows:

President—Roland B. Dixon, Harvard University.

Vice-president 1914—George A. Dorsey, Field Museum of Natural History.

Vice-president 1915—Alexander F. Chamberlain, Clark University.

Vice-president 1916—A. L. Kroeber, University of California.

Vice-president 1917—George B. Gordon, University of Pennsylvania.

Secretary—George Grant MacCurdy, Yale University.

Treasurer—B. T. B. Hyde, New York.

Editor—F. W. Hodge, Bureau of American Ethnology.

Associate Editors—John R. Swanton, Robert H. Lowie, and Alexander F. Chamberlain.

The following is a list of the addresses and papers presented:

"The Pittdown Skull," by Charles H. Hawes.

"Ten Days with Dr. Henri Martin at La Quina (Charente), France," by Charles Peabody.

"Paleolithic Art as represented in the American Museum of Natural History, New York," by George Grant MacCurdy.

"The So-called 'Argillites' of the Delaware Valley," by N. H. Winchell.

"Results of an Archeological Survey of the State of New Jersey," by Leslie Spier.

"The So-called Red Paint People Cemeteries of Maine," by Warren K. Moorehead.

"Stone Implements of Surgery (?) from San Miguel Island, California," by H. Newell Wardle.

"Etruscan Influence in West Africa and Borneo," by Earnest Albert Hooton. (By title.)

"Brief Account of Recent Anthropological Explorations under the Auspices of the Smithsonian Institution and Panama-California Exposition," by Ales Hrdlička.

"Results of Excavations at Machu Picchu," by Hiram Bingham.

"The Human Monster-figure on the Nazca Pottery," by Edward K. Putnam.

"Note on the Archeology of Chiriqui," by George Grant MacCurdy.

"The Maya Zodiac at Acanceh," by Stansbury Hagar.

"Chinese Antiquities in the Field Museum," by Berthold Laufer.

"Some Aspects of North American Archeology," presidential address, by Roland B. Dixon, followed by a symposium: "The Relation of Archeology to Ethnology," by Franz Boas, W. H. Holmes, Berthold Laufer, George Grant MacCurdy.

"The Horse and the Plains Culture," by Clark Wissler.

(a) "Wayside Shrines in Northwestern California"; (b) "Is there Evidence, other than Linguistic, of Relationship between the Northern and Southern Athapascans?" by P. E. Goddard.

"Phratries, Clans, Moieties," by Robert H. Lowie.

"The Social, Political and Religious Organization of the Tewa," by H. J. Spinden.

"Tewa Kinship Terms from the Village of Hano, Arizona," by Barbara Freire-Marreco. (By title.)

"The Cultural Position of the Plains Ojibway," by Alanson Skinner.

"Results of Some Recent Investigations Regarding the Southeastern Tribes of the United States," by John R. Swanton.

(a) "Notes on Alonquian Grammar"; (b) "Notes on the Social Organization of the Fox Indians," by Truman Michelson.

"My Experiences in the South Seas," by A. B. Lewis. (By title.)

"Field Work Among the Pagan Tribes of the Philippines," by Fay Cooper Cole.

"The Sac-sac or Human Sacrifice of the Bagobo?" by Elizabeth H. Metcalf.

"The Boomerang in Ancient Babylonia," by James B. Nies.

(a) "The Huron and Wyandot Cosmogonic Deities and the Iroquoian Sky Gods"; (b) "The Wyandot Ukis," by C. M. Barbeau.

"The Clan and the Maternal Family of the Iroquois League," by A. A. Goldenweiser.

"Daily Life of the Southern Pai-Utes Forty Years Ago," by Frederick S. Dellenbaugh.

"The Physical Type of the Burusheki of the Northern Himalaya," by Roland B. Dixon.

"The Eruption and Decay of the Permanent Teeth," by Robert B. Bean. (By title.)

"A Piebald Family of White Americans," by Albert Ernest Jenks.

"Condition Favoring the Development of Totemic Organization," by Franz Boas.

"Outline of the Morphology and Phonetics of the Keresan Dialect," by J. P. Harrington. (By title.)

"The Relation of Winnebago to Plains Culture," by Paul Radin. (By title.)

"Types of American Folk Songs," presidential address, by John A. Lomax.

"A Folk Dance from the Charente, France," by Charles Peabody.

"The Crow Sun Dance," by Robert H. Lowie.

"Notes on the Folk-Lore and Mythology of the Fox Indians," by Truman Michelson.

"Iroquois Totemic Complex," by A. A. Goldenweiser.

"Home Songs of the Tewa Indians," by H. J. Spinden.

"The Ballad in South Carolina," by Reed Smith.

"Negro Lore in South Carolina: (a) Tales, Sayings and Superstitions; (b) Songs, A Plantation Dance befo' de War," by Henry C. Davis.

"The Bridge of Sunbeams," by Phillips Barry.

"The Japanese New Year," by Mock Joya.

(a) "Siuslauan, a Newly Discovered Linguistic Family"; (b) "An Ethnological Sketch of the Wailatpuan Tribes of Northeastern Oregon," by Leo J. Fraetenberg. (Both by title.)

"Some Aspects of the Folk-lore of the Central Algonkin," by Alanson Skinner.

"An Introduction to the Study of Indian Religion," by Paul Radin. (By title.)

THE EVOLUTION OF A BOTANICAL PROBLEM

THE HISTORY OF THE DISCOVERY OF SEXUALITY IN PLANTS¹

FROM the beginning of man's thoughtful consideration of natural processes, the phenomenon of sexual reproduction, with the associated phenomena of heredity, have persistently engaged his keenest interest. The primary fact of the necessary concurrence of two individuals in the production of offspring was, in the case of animals, recognized from the beginning. The equivalent phenomenon was not established for plants until the end of the seventeenth century. At this time, however, little more was known of the essential features of the sexual process in animals than had been familiar to Assyrians, Egyptians and Greeks twenty centuries before.

Of the additions made since 1700 to our knowledge of sexual reproduction, of its varied types and of the associated phenomena, no mean share has been contributed by botanical investigators. Noteworthy among such contributions are the work of Koelreuter and Mendel in the production and systematic study of plant hybrids, and the early work of Pfeffer on the chemotactic response of spermatozooids. Of more recent work we may cite that of the plant cytologists on apogamy and apospory, on multi-nucleate sexual cells or gametes, and on the long-delayed nuclear fusion in the sexual reproduction

¹ Address of the vice-president and chairman of Section G, Botany, American Association for the Advancement of Science, December, 1913.

of the plant rusts. It should then be of interest for us to consider just how and when the more important steps have been taken in building up the vast mass of somewhat incomplete knowledge that we now possess concerning the reproductive process in plants. Because of exigencies of time and patience, I shall confine myself primarily to an attempt to picture the chief steps by which our present knowledge of the essential sexual process, the union of two parental substances, has been attained. Incidentally we may note the changes in point of view of investigators and in their mode of attack on this problem. I shall attempt to suggest the trend of development more clearly by often grouping the chief phenomena discovered in such a way as to indicate the sequence of discovery, within each group, of the different phases of the sexual process, though the order of discussion may thus not always accord with the sequence, in time, of the discovery of individual phenomena in plants as a whole.

In following the evolution and change in aspect of our problem we shall often find it best to keep a few relatively great names prominent. This will serve in the first place to make the story more vivid and intelligible. It will at the same time often come nearer the essential truth, for in each great forward step some one worker has usually been the dominating leader.

I. THE DISCOVERY THAT POLLINATION IS A PREREQUISITE TO SEED-FORMATION.

750 B.C. TO A.D. 1849

The first discoveries pointing to the existence of sex in plants were evidently made very early in human history by peoples cultivating unisexual plants for food. The existence of fertile and sterile trees of the date palm, *e. g.*, was known to the peoples of Egypt and Mesopotamia from the

earliest times. Records of the cultivation of these trees and of artificial pollination have come down to us on bas-reliefs from before 700 B.C. found in the palace of Sargon at Khorsabad (Haupt and Toy, 1899). The Assyrians, it is said, commonly referred to the two date trees as male and female (Rawlinson, 1866). The Greeks, in spite of their peculiarly keen interest in natural phenomena, failed to offer any definite interpretation of this well-known fact concerning the date palm. Aristotle and Theophrastus report the fact, gained apparently from the agriculturalists and herb-gatherers, that some trees of the date, fig and terebinth bear no fruit themselves, but in some way aid the fertile tree in perfecting its fruit. But without recording a single crucial experiment on the matter, Theophrastus concludes that this can not be a real sexuality, since this phenomenon is found in so few plants.

In this uncertain state the knowledge of sexuality in plants was destined to rest for twenty centuries, waiting for the experimental genius of Camerarius to give a conclusive answer to the question raised by the Assyrian and Greek gardeners and answered wrongly by Theophrastus. The English physician Grew (1676) did, it is true, accept and expand the suggestion of Sir Thomas Millington that the stamens serve as the male organs of the plant. Thus Grew concludes (p. 173) that when the anther opens the "globulets in the thecae act as vegetable sperm which falls upon the seed-case or womb and touches it with prolific virtue." But this guess, though it proved correct in the main point, was still a guess, and not supported by any critical evidence so far as recorded by Grew. The only adequate evidence that could be obtained on this question, while microscopes and technique were still so imperfect, was experimental evidence. This kind of proof

was first given, some 20 years after Grew's work, by Rudolph Jakob Camerarius, of Tübingen. Camerarius fully appreciated the presence of a real problem here. He also had the genius to see that the philosophical attempts of many of his immediate predecessors, to discover its solution entirely in their own inner consciousnesses, were futile. With the insight of a modern experimenter Camerarius put the question to the plants themselves. The results of his experiments, as reported in the famous letter of 1694 to Professor Valentin, of Giessen, were clear and conclusive. After noting that aborted seeds were produced by isolated—and therefore unpollinated—female plants of *Mercurialis*, and of the mulberry; by castrated plants of the castor bean; and by plants of Indian corn from which he had removed the stigmas, Camerarius gives his interpretation of these phenomena. He says (Ostwald "Klassiker," p. 25):

In the vegetable kingdom there is accomplished no reproduction by seeds, that most perfect gift of nature, and the usual means of perpetuating the species, unless the previously appearing apices of the flower have already prepared the plant therefor. It appears reasonable to attribute to these anthers a noble name and the office of male sexual organs.

In the seventy years after Camerarius had proved in this way the existence of two sexes, and the fertilizing function of the pollen in plants, little advance was made. Bradley, of London, Gleditsch, of Berlin, and Governor Logan, of Pennsylvania, confirmed parts of Camerarius's work, and the great Linnæus accepted the conception of the stamens and pistils as sexual organs as clearly proven, *not*, be it noted, *by the results of Camerarius's experiments* but by "*the nature of plants.*"

In 1761, J. G. Koelreuter, of Carlsruhe, published an account of the first systematic attempt that had been made, with

either plants or animals, to produce and carefully study artificial hybrids. In his work with hybrid tobaccos, he demonstrated that characters from both parents are often associated in a single offspring. He thus not only completed Camerarius's work, but also, by showing that the male parent participates in the makeup of the offspring, he helped materially to break down the "emboitement theory" of Christian Wolff, which assumed that the embryo came entirely from the egg, and that its characters could not be influenced by the male parent. It is true that Koelreuter was mistaken in believing that fertilization is accomplished by the mingling of the oil on the pollen grains with the secretion of the stigma to form a mixed fluid, which he supposed then penetrated to the ovule. Nevertheless, his conception of the mingling of two substances was a move with the proper trend.

Koelreuter also demonstrated that in nature the pollen necessary to fertilization is often brought to the stigma by insects. He thus opened up a field of research which was cultivated with such splendid effect by Konrad Sprengel thirty years later, and by Darwin, Müller and others a century afterward.

In spite of the absolutely conclusive work of Camerarius, Koelreuter and Sprengel on the sexuality of plants, their conclusions were often rejected during the first half of the nineteenth century. Certain devotees of the nature philosophy, for example, occupied themselves either in proving over again, after Cesalpino, that plants can not be sexual, *because of their nature*, or in trying, by ill-conceived, and carelessly performed "experiments," to prove the conclusions of Camerarius and Koelreuter erroneous. These objectors were finally silenced, however, when Gaertner, in 1849, published the results of such a large num-

ber of well-checked experiments, entirely confirming the works of Camerarius, Koelreuter and Sprengel, that no thinking botanist has since doubted the occurrence in flowering plants of a sexuality essentially identical with that found in animals.

II. THE DISCOVERY OF THE POLLEN TUBE AND ITS RELATION TO THE ORIGIN OF THE EMBRYO, 1823-1847

During the opening years of the nineteenth century a number of botanists, who believed in the sexuality of plants, tried to discover by the aid of the microscope just how fertilization is effected. Most botanists of the day believed the pollen grain burst on the stigma, and that its granular contents found a way through the style to the ovary. An entirely new aspect of the problem of fertilization was opened up, however, when in 1823 Amici, of Modena, saw on the stigma of *Portulacca*, young pollen tubes arising from the pollen grains. Seven years later he followed these tubes through the style to the micropyle of the ovule. At about this time also, Jakob Matthias Schleiden (1838) took up the study of this same problem. He was a man of vigorous intellect and great versatility, who sometimes misinterpreted what he saw, but who proved a most stimulating opponent to a number of other workers who did observe accurately. After denying Robert Brown's assertion that the pollen tubes of the orchids arise in the ovary, Schleiden proceeded to describe and figure the pollen tube as penetrating, not merely the style and then the micropyle, but even far into the embryo sac itself.

Here, as he says in his *Grundzüge* (II., p. 373):

The end (of the pollen tube) soon swells, either in such a way that the vesicle arising in it fills the whole cavity of the portion of the tube within the embryo sac, or there is left, between the apex of

the embryo sac and the embryonal vesicle of the tube, a long or a short cylindrical portion of the latter, the suspensor.

He thus regarded the embryo sac as a sort of hatching place for the embryo which he thought formed from the end of the pollen tube. This idea of the origin of the embryo really denied the occurrence of any actual sexual process, and made the pollen the mother of the embryo.

In 1846, however, the error of this conception was clearly demonstrated by Amici, who showed that the embryo of the orchids arises from an egg which is already present in the embryo sac when the pollen tube reaches it. It is this pre-existing egg, according to Amici, that is stimulated to form the embryo by the presence near it of the pollen tube. This view was confidently supported by Mohl (1847) and Hofmeister (1847) in the following year, and the controversy with Schleiden became even more spirited. As Mohl afterward wrote (1863), men were "led astray by their previous conceptions to believe they saw they could not have seen." The dispute even approached the acrimonious, as when Schleiden (1843) says of one worker's figures, "Solche Präparate sind ohne Zweifel aus den Kopf gezeichnet."

Hofmeister, from the beginning of his study of fertilization in seed plants, had sought in the pollen tube for some equivalent of the spermatozoids, those motile male cells of the mosses and ferns that had first been understood by Unger in 1837. He was unable, however, to do more than point out the mistake of earlier observers in regarding the starch grains of the pollen tube as spermatozoids, and to suggest the likelihood that these motile cells might be discovered in the gymnosperms, a prediction the fulfilment of which was realized by Ikeno and Webber fifty years later. In his study of pollen tubes Hofmeister

demonstrated to his own satisfaction that the tube does not open in accomplishing fertilization. His view, which was the one current till 1884, was that the egg is stimulated to develop into the embryo by some substance that diffuses through the *imperforate* wall of the pollen tube.

III. THE DISCOVERY OF A PROTOPLASMIC FUSION AT FERTILIZATION

We come now to consider a series of discoveries of supreme importance in the investigation of the essential sexual process in plants. This is the period in which the problem that had baffled naturalists for twenty centuries was at last solved, at least in one most essential feature, by the demonstration of the occurrence at fertilization of a mingling of paternal and maternal substances.

It will not be without interest at this point to note the intellectual stimuli which led an unusual number of workers to investigate this phase of our problem.

In the first place there were on record, and under discussion at the middle of last century the many puzzling observations of the "Spiral Faden," or animalculæ, as they were thought to be, that had been found arising from a number of plants. These motile, spiral filaments had been seen in a liverwort (*Fossombromia*) by Schmiedel (1747), in *Sphagnum* by Esenbeck (1822), in *Chara* by Bischoff (1828), and finally, on the fern prothallus by Naegeli (1844). Unger (1834-37) studied these bodies in the mosses (*Sphagnum* and *Marchantia*) and declared his belief that they are not infusoria, but are the male fertilizing cells. At this time also the zoologists of the day were making the first detailed studies of the spermatozoa of animals. Barry (1844) had seen a spermatozoon within the egg of the rabbit; Leuckart (1849) saw them enter the frogs'

egg and then, in 1851, Bischoff and Allen Thompson proved that fertilization is accomplished by the actual entrance of the spermatozoon into the egg. A no less important influence, in stimulating the botanical workers on the problem of fertilization, was the magnificent work of Hofmeister, on the reproductive structures of the mosses, ferns and conifers. By these splendid researches he had indicated to men of less insight, and less comprehensive imagination, just the points in the life cycles of plants where the critical phases of the reproductive process are to be sought.

Among the many workers engaged on this problem of fertilization in plants in the third quarter of last century there was, in consequence of readier exchange of information, an attitude of greater consideration for the work of other investigators than was found in the two preceding decades. There were differences of opinion and interpretation, to be sure, but there was less of that strenuous cocksureness when men saw, or thought they saw, differently from others. The mistakes of the brilliant Schleiden were perhaps remembered. Men like Hofmeister, Pringsheim and Strasburger added to and modified the interpretations of other workers in the same spirit with which they remolded their own immature conclusions. There was a spirit of cooperation evident; it became possible for a worker to observe and record the fate of a pollen tube in good temper and with calm judgment.

The first steps toward the demonstration of a union of two masses of living substance at fertilization resulted from the study of a group of plants, the algæ, in which sexuality had not been proven or generally admitted. It had, however, long before, been suggested in the case of *Spirogyra* by Hedwig (1798) and Vaucher (1803).

The algæ were in fact especially advan-

tageous for the study of fertilization, since the development and behavior of the reproductive organs and cells could, without elaborate preparation, be readily seen under the microscope, and often followed through in living material. Thus, Thuret in 1853 for the first time saw the active sperms attached to the egg of *Fucus*, and in 1854 proved experimentally that only eggs to which spermatozooids have had access will germinate. He thus demonstrated in this alga the correctness of Unger's unsubstantiated surmise (1837) that the spermatozooids are the male fertilizing cells. In *Ædogonium*, Pringsheim, in 1856 (p. 9), watched the spermatozoid push into the receptive tip of the living egg and saw the characteristic oospore wall formed in consequence. This, except for the less satisfactory observations made on *Vaucheria* by the same worker a year previous, is the first case recorded of the observation of the actual union of male and female cells in any plant. Such a union of the protoplasmic masses of the two sexual cells was soon shown to be a characteristic feature of fertilization in a number of algae. Thus de Bary saw it in *Spirogyra* (1858), and Pringsheim (1869) repeatedly observed the gradual fusion of the motile gametes of *Pandorina*. It was nearly thirty years later, however, that this phase of fertilization was first seen in seed-plants by Goroschankin and Strasburger.

The workers on this problem were on the lookout for further details of the process of fusion, and even knew rather definitely what they were looking for, but failed to discover it from lack of proper methods of preparation of material. Thus, *e. g.*, Strasburger, in 1877, carefully studied the process of conjugation in *Spirogyra* and found that "Hautschicht fuses with Hautschicht, Kernplasma with Kernplasma"—"The chlorophyll bands unite by their ends"—

and then goes on to say of the feature that evidently interested him most, "the cell nuclei of both cells, however, become dissolved; the copulation product is without a nucleus." Two years later, Schmitz (1879), when studying hematoxylin-stained material of this alga, was more fortunate. He saw the two nuclei in the zygote, as he says, "approach nearer and nearer, come into contact and finally fuse to a single nucleus." This observation by Schmitz is an important one, for in it we have the first clear statement that the nucleus of the male cell passes over intact to the female cell, there to fuse with the female nucleus.

Strasburger had, it is true, seen a second nucleus fusing with that of the egg in the archegonia of *Picea* and *Pinus* in 1877. He did not, however, really know the source of this second nucleus, though he suspected some relation to those that are present earlier in the tip of the pollen tube. These tube nuclei he says are dissolved just before fertilization, and then just after fertilization, to quote (1877):

The male nucleus formed from the contents of the pollen tube is found now near the end of the tube, now near, or in contact with, the egg nucleus. . . . The protoplasmic contents of the pollen tube, I hold, passes through the (imperforate) tube-membrane in a diosmotic manner.

The fertilization of the gymnosperms, because of their large eggs, pollen tubes and nuclei, was then being studied by a number of workers. One of these, Goroschankin, in 1883, was able to demonstrate that in *Pinus pumilio* the pollen tube opens at the end, and that through this pore the two male cells pass bodily into the egg. Goroschankin's mistake, in supposing both male nuclei to fuse with the egg nucleus, was corrected by Strasburger the following year. The latter (1884) saw the same bodily exit of both male nuclei from the open pollen tube of *Picea*, but found only

one male nucleus fusing with that of the egg. In the same publication Strasburger also records numerous instances in which he had been able to observe the same mode of escape of the contents of the pollen tube into the ripe embryo sac in angiosperms. At last, as Strasburger puts it, in discussing fertilization in the conifers:

The most important morphological facts are clear. It is established that the male nucleus that copulates with the egg nucleus, passes *as such* out of the pollen tube into the egg.

Thus, finally, was the actual material contribution of both parents to the embryo of the seed plants first seen. This was just two centuries, lacking a decade, after Camerarius (1694) had proven that the presence of pollen on the stigma is indispensable to seed formation. One chief reason why this important problem so long baffled all investigators was the lack of proper methods of preparing material for study. The older method of studying unfixed and unstained sections had certain advantages, it is true. The sequence of developmental stages was often determined with certainty by actually following their succession in living material under the microscope, and there was less cause also for dispute about artifacts. But structures of the same refractive qualities were not readily distinguished in such sections. As Strasburger himself says (1884, p. 18):

The negative results of my earlier studies and of those of Elfving were due to the lack of a method which permitted the nuclei to be distinguished in the strongly refractive contents of the pollen tube up to the moment of fertilization.

That these studies of 1884 were successful was largely due to the use of material fixed in five-tenths-per-cent. acetic acid, one-per-cent. osmic acid or absolute alcohol, and stained in borax carmine, hematoxylin or iodine green.

The extreme significance of the fact that those most highly organized portions of the

cell substance—the nuclei—were so prominent in the process of fertilization was at once appreciated by Strasburger, who in 1884 (p. 77) announced the following general conclusions as the outcome of his consideration of the phenomena observed:

(1) The fertilization process depends upon the copulation with the egg nucleus of the male nucleus that is brought into the egg, which is in accord with the view clearly expressed by O. Hertwig. (2) The cytoplasm is not concerned in the process of fertilization. (3) The sperm nucleus like the egg nucleus is a true cell nucleus.

In the years since 1884 the nuclei have been found to be the structures chiefly concerned in fertilization whenever such a process occurs. Among the earlier observations of this nuclear union at fertilization in each of the great groups are the following, named in the order of discovery: It was seen in *Pilularia* (Campbell, 1888), in *Riella* (Kruch, 1891), in *Edogonium* (Klebahn, 1892), in the plant rusts (Dangeard and Spain-Trouffy, 1893), in the toad-stools (Wager, 1893), in the red alga *Nemalion* (Wille, 1894), in *Sphaerotheca* (Harper, 1895), in the rockweed, *Fucus* (Farmer and Williams, 1896). Finally Zederbauer (1904) reported it for the Peridinea and Olive (1907) and Kraenzlin (1907) made it out in the myxomycetes.

The observations just referred to, and many others on plants in all groups, warrant the general application of Strasburger's conclusion that a nuclear union is the characteristic feature of every sexual process. The few cases where the male cytoplasm seems more prominent than usual, as in the three conifers studied by Coker (1903), Coulter and Land (1905) and Nichols (1910), can not yet be said to have rendered it very probable that this cytoplasm plays a primary part as an inheritance carrier.

IV. THE DISCOVERY OF THE ALTERNATION OF GENERATIONS IN PLANTS, 1851-

The fact that the sexual cells of the higher plants are produced on a plant body or individual distinct from that which forms the asexual reproductive cells; and that in the normal life cycle the one type of individual arises from, and later gives rise to, an individual of the other type, must be regarded as one of the most significant features of the evolution of plants yet discovered. One of the chief general results of the magnificent work of Hofmeister was the discovery of this regular alternation of a sexual and an asexual generation, not only in the life history of the mosses and ferns, but also in that of the seed plants. Hofmeister states this result clearly in the *Vergleichende Untersuchungen* and makes it apply still more broadly in a brilliant generalization published in the "Higher Cryptogamia." There he says (p. 439):

The phenogams, therefore, form the upper terminal link of a series, the members of which are the Coniferæ and Cycadææ, the vascular cryptogams, the Muscinæ and the Characææ. These members exhibit a continually more extensive and more independent vegetative existence in proportion to the gradually descending rank of the generation preceding impregnation, which generation is developed from reproductive cells cast off from the organism itself.

Since Hofmeister's day detailed investigations by many workers have fully confirmed Hofmeister's conclusion. They have shown the essential homology, not only of the spore-producing organs, and the one or two kinds of spores produced in them, but also of the structures arising from these spores, throughout all cormophytes, from the mosses upward.

In the studies of the algæ that followed immediately after Hofmeister's work, investigators of these plants sought in them for some evidence of that regular alternation of sexual and asexual phases that had

been demonstrated in higher plants. Pringsheim (1856, p. 14) one of the ablest of these students of the algæ, at first regarded the multicellular body, formed at the germination of the oospore of *Edogonium* and *Coleochaete*, as an asexual phase, comparable with the simple sporophyte of the liverwort *Riccia*. Celakowsky (1886) distinguishes as *homologous alternation* those cases, in algæ, like *Ulothrix* or *Edogonium*, where the gamete-producing generation seemed capable of zoospore production also. The constant and regular alternation of the archegoniates and seed plants he called *antithetic alternation*. Pringsheim (1877) found that moss protonemata form from cuttings of the seta of the sporophyte as well as from bits of the gametophyte. From this fact, and from Farlow's discovery (1874) that a sporophyte of the fern, *Pteris cretica*, may arise directly from the prothallus, without the fertilization or even the formation of an egg, Pringsheim concluded that both generations of the archegoniates are really identical. He says (1877, p. 6):

I believe the moss sporogonium stands to the moss plant in the same relation that the sporangium-bearing *Saprolegnias* do to the oogonium-bearing plants of this species, . . . I therefore turn against this interpretation of the fruit generation of the thallophytes in general, and especially against this interpretation of the sexual shoot generation of the Floridææ and Ascomycetes. . . . The cystocarp is evidently not a *separate* individual but part of the sexual plant that produces it.

The antithetic view was reasserted, however, especially by Celakowsky (1877) and Bower (1890), both of whom emphasized the suggestion of A. Braun (1875) that the sporophyte is a new thing phylogenetically. Bower holds that the types of sporophyte found in the archegoniates have arisen by the amplification of the zygote, with the sterilization for vegetative functions of

smaller or larger portions of the originally all-pervading sporogenous tissue. The amphibious type of alternation of the mosses and ferns has arisen, according to Bower's conception, with the migration of these plants to the land, and the assumption of the terrestrial habit by the sporophyte. The antithetic view was also supported in a most striking way, later, by the results of the workers on chromosomes.

The homologous view of alternation also has not been without supporters in the years since Pringsheim. One of its upholders, Klebs (1896), based his belief on the fact that he could determine the type of reproductive cells formed by the algæ *Hydrodictyon* and *Vaucheria*, by changing the conditions under which they are grown. Lang (1896-98) favored the homologous view because of the discoveries of Farlow, de Barry, Bower, Farmer and himself on apogamy and apospory. Scott, one of the strongest advocates of the homologous alternation theory, bases his belief not only on the evidence afforded by the cases of apogamy and apospory, but also on the fossil record. He points out the lack of any sporophyte, living or fossil, that can be regarded as ancestral to that of the ferns. In arguing for the homologous origin of the leafy fern sporophyte from a liverwort-like thallus Scott says (1911):

We know plenty of intermediate stages between a thallus and a leafy stem; but no one ever saw an intermediate stage between a sporogonium and a leafy stem.

V. THE DISCOVERY OF CHROMOSOME REDUCTION AND OF SYNAPSIS, 1888—

We have seen that during the two decades at the middle of last century students of sexuality in plants devoted their attention to the discovery of the relation of the pollen tube to the origin of the embryo. The three decades after 1860 were given

largely to the proof of a union of a paternal with a maternal nucleus as a constant feature of the sexual process in plants. For the past two decades workers interested in reproduction have been engaged especially in determining the behavior and fate, in the various phases of plant development, of those essential elements of the nuclei, the chromosomes. The result of this study has been to give us a much more definite criterion than we had before, of just what constitutes a sexual process. Moreover, this intimate examination of the chromosomes, together with the precise means of germinal analysis by breeding, introduced by Mendel, has given us some insight into the significance of the sexual process in the ontogeny and phylogeny of plants.

The discovery of chromosomes in plants may best be attributed to Strasburger, who, in 1875, first figured them distinctly in the embryo of *Picea*. It is true that Hofmeister (1867) had noticed the equatorial plate of "albuminous clumps" in cells at the time of their division, and Russow (1872) saw, in the dividing spore mother-cell nuclei of *Ophioglossum*, plates of vermiform rods ("Stäbchenplatten"). Strasburger (1879) and Hanstein (1880) and Flemming (1880) were, however, the first to realize the constancy of the occurrence of chromosomes in the dividing plant nucleus. The fact soon pressed itself upon investigators that the number of these chromosomes differs in different plants, and in different phases of the same plant. Then followed the epoch-making discovery of the zoologist Van Beneden (1883), that the number of chromosomes in the egg and sperm of *Ascaris* is the same, and that the double number characteristic of the body cells becomes reduced during the maturing of the germ cells. Botanists after some delay, due, as Strasburger says, to lack of proper technique, succeeded in demonstrat-

ing these same facts for plants. Thus Strasburger in 1888 showed that the number of chromosomes characteristic of the egg and of the male nucleus in a number of angiosperms is the same, and is fixed by a reduction, occurring in the mother cells of the pollen and of the embryo-sac. Guignard also (1889 and '91) demonstrated these phenomena in *Lilium* and in the pollen mother cells of *Ceratozamia*, noting the eight double chromosomes in the latter and other peculiarities of the first mitosis. Overton (1893) counted the same number of chromosomes in the female prothallus of *Ceratozamia*; while Farmer (1894) found four chromosomes in the thallus and sexual reproductive cells of *Pallavicinia* and eight in the seta and capsule.

Later in the same year Strasburger, in a masterly address before the British Association, completed the proof of Overton's suggestion (1893) that reduction in the mosses and ferns also takes place, as Overton puts it, "in the mother-cells of the spores; that is, at the point of alternation of the generations." Strasburger, by comparing his counts of chromosomes in the dividing spore mother cells of *Osmunda*, with the number seen by Humphrey (figures published in 1895) in the tapetal cells, found the latter number about double. It is interesting to note also that the *Osmunda* slides used in this work were among the first paraffin sections used by Strasburger.

From this correspondence of the liverwort and fern mentioned with the seed plants in which reduction had been seen, Strasburger went on to predict the universal occurrence of this phenomenon of reduction in all plants that reproduce sexually. Concerning the phylogenetic origin of the reduction process Strasburger held that all plants (and animals) were primitively non-sexual and had a constant number of chromosomes. With the development of

sexual reproduction the initiation of the process of chromosome reduction avoided the evident disadvantage of repeated doubling of the chromosome number at each sexual fusion. This return from the double number formed in the zygote to the primitive, ancestral number of chromosomes, he believed might occur at any point in the life cycle before the next fertilization. Strasburger then went on to emphasize the advantage of the sexual mode of reproduction, when once acquired, in allowing new combinations of parental strains in the offspring, and the disadvantage it had of producing so small a number of offspring. It is to meet this disadvantage, he suggested, in agreement with Bower, that the zygote of forms like *Coleochaete*, mosses, ferns and seed plants took over the function of multiplying the progeny by a sort of polyembryony, the formation of spores. The spore-bearing generation later in the evolutionary history became ultimately independent of the gametophyte, and at a still later period it not only produced two kinds of spores, but also assumed the care and nutrition of the reduced female plant, arising from the larger of the two kinds of spores. Thus, in Strasburger's view, the primitive non-sexual generation is now represented in the archegoniates by only the sexual phase which has gradually lost its power of asexual multiplication, while the sporophyte is a third, a new, generation arisen by specialization of the zygote. There is in the cormophytes then an antithetic alternation of the two most recently evolved phases of the life cycle, while the only clear trace of the primitive non-sexual phase is found in the halved number of chromosomes, which is reverted to by a process of chromosome reduction, at some point in each life cycle.

In the two decades since this famous pronouncement of Strasburger's was made

chromosomes have been counted in the different developmental phases of nearly all groups of plants. These counts have shown that wherever there is sexual fusion there is also, at some other point in the life cycle, a reduction of the double number of chromosomes so formed to the single number characteristic of the gametes. In all eucormophytes and many thallophytes this reduction occurs at sporogenesis.

The investigation of the complementary phase of the chromosome behavior, the doubling of the number at fertilization, has during the past two decades also led to extremely interesting results.

The earlier workers on sexual nuclear fusion apparently believed that the paternal and maternal nuclear materials became intimately mingled soon after contact of the nuclear walls. Thus Klebahn (1892) described the chromatin reticula of the two nuclei as gradually merging into one, in *Edogonium*, and Shaw (1898) described the same process in *Onoclea*. It is true that Guignard (1891) had noted that, in *Lilium* and *Fritillaria*, the male and female reticula remain distinct until the prophase of the first nuclear division of the embryo. Later research, however, showed that the paternal and maternal components remain distinct till much later than this; in fact, that the chromatin elements from the two parents do not really fuse at all during the process of fertilization. On the contrary, it is pretty certain that all through the development of the sporophyte the chromosomes from the two sources retain their identity and individuality.

Thus Blackman (1898) and Ferguson (1901) say that in the fusing nuclei of *Pinus* the two chromatin nets never lose identity, and that at the first mitosis of the embryo each constituent gives rise to its own group of chromosomes. This independence of the two chromatins at fertili-

zation has since been seen in a number of species, and it is now believed to persist throughout the life of the sporophyte. The double number of chromosomes is present at each mitosis of this generation, and they sometimes occur in pairs that are assumed to consist of a paternal and a maternal chromosome each. In certain plants also, according to Overton (1909), Grégoire (1910), Stout (1912) and others, the individuality of the chromosomes of the resting nucleus, postulated by Strasburger in 1894, is morphologically discernible. De Vries (1903) emphasized this fact, that the sporophyte, with its two complete sets of chromosomes, is really two beings in one, by designating it as the "2X generation." This contrasts it at once, in this important characteristic of chromosome number, with the gametophyte or "X generation."

Apparently then no actual fusion of the chromosomes is included in the nuclear union occurring at fertilization. The question at once arising is: where in the life cycle is there any fusion, or intimate union of these inheritance-bearing units? The answer to this question was for some time generally believed to be offered by the phenomena associated with the process of "synapsis." Botanists had for some time noticed and figured the peculiar contraction of the chromatin of the spore mother-cell nucleus occurring just before the chromosomes for the reduction division are formed. Moore (1895) reaffirmed Strasburger's view that, even with the best preservation, the chromatin regularly assumes this condition at sporogenesis, and then only. Moore, therefore, declared this condition to be, not an artifact, as many workers had held, but a natural process, which he named "synapsis." In spite of the insistence by an occasional worker that synapsis is an artifact, the impression of its constancy and peculiarity grew more

general at the end of the last century. Then in 1901 Montgomery suggested that it is in this process that the long-delayed union of the paternal and maternal chromatin occurs. Montgomery's conception, that each of the double or bivalent chromosomes, formed on emergence from synapsis, is made up of a paternal and a maternal chromosome, which have in some way been paired up during the synaptic process, came to be rather generally accepted.

Recently, however, a number of workers have dissented vigorously from the view that synapsis is a constant, or a highly significant process. Thus Gregoire (1910), Gates (1911) and Lawson (1912) hold that it does not occur unfaithfully at sporogenesis. Lawson says that so much of the separation of the chromatin from the nuclear wall as is not due to artifact is attributable to the more rapid growth of the nuclear wall than of the chromatin. Finally all three agree that such a process is not needed for the pairing of the chromosomes, since, as was observed by Strasburger (1905) and others, the chromosomes may regularly appear in pairs in the vegetative mitoses of the sporophyte. Moreover studies of the vegetative nuclei of the sporophyte, especially by Gregoire and his students, show that their chromosomes are closely connected by adhesions, and by pseudopodium-like strands developed between the viscid chromosomes when the new reticulum is formed after each mitosis. Gates (1911) after reviewing recent work on this point holds that the pairs seen in vegetative mitoses are of a paternal and a maternal chromosome each. He sees no adequate reason for thinking that the association of parental chromosomes at synapsis is any more intimate than that which occurs, as he says, "at or soon after fertilization." He evidently regards the connections between sporophytic chromosomes

referred to above as affording ample opportunity for any interchange of material or "influences" between the chromosomes. Gates does not say just when the parental chromosomes are first paired up after fertilization nor give the evidence for this. He fails, also, to explain the fact, upon which practically all workers seem agreed, that the halves of the diploid chromosomes are associated with each other in a more intimate way than the chromosomes of any other mitosis in the life cycle.

VI. ALTERNATION AND CHROMOSOME NUMBERS IN THE ALGÆ, 1896-

We have already seen that an attempt was made in the third quarter of last century to interpret the life histories of certain thallophytes, especially among the algæ, in terms of the alternating generations discovered by Hofmeister among the archegoniates. The basis of comparison was the occurrence of a sort of polyembryony at the germination of the sexually produced oospore of these algæ. There was much uncertainty, however, concerning the real correspondence of phases in the two groups, and even as to whether the alternation was of the same sort in the two groups.

With the promulgation of Strasburger's view (1894) regarding the significance of the reduction of the chromosome number in the life cycle, botanists felt that they would now be able to distinguish the phases of a real alternation of generations wherever chromosomes could be counted. A number of workers therefore followed out cytologically the details of development and conjugation of the sexual cells, and the germination of the zygote in various algæ.

The work of Chmielewski (1890), on *Spirogyra*, and of Klebahn (1891) on desmids showed some indications of a reduction process at the germination of the

zygote in these forms, though chromosomes could not be counted. Not till very recently was it demonstrated for one of these, *Spirogyra*, that the chromosome number is actually reduced at this time. Tröndle (1911) has counted chromosomes of *Spirogyra* and finds that there is a real reduction here, and that three of the first four nuclei formed in the zygote degenerate, the fourth remaining as the nucleus of the single embryonic plant formed.

In a study of the green alga, *Coleochate*, Allen (1905) showed that the chromosome reduction occurs with the beginning of germination of the zygote. Hence the group of zoospore-producing cells, arising from the latter, is not to be regarded as a sporophyte, as had often been maintained. Allen thus eliminated the only ancestral prototype of the bryophyte sporogonium that the antithetic alternationists had been able to discover among the green algae.

The search among the brown algae for parallels to the chromosome history of the cormophytes has been much more successful. The first case made out, that of *Fucus*, by Farmer and Williams (1896) and by Strasburger (1897) seemed, it is true, not very illuminating. They found the reduction occurring in the first divisions of the eggs and sperm-producing organs, a point where it occurs in no other green plant. This case of *Fucus*, you will remember, is the one used by Scott (1896) to point a moral, when voicing the generally felt criticism of those botanists who proposed "making the number of chromosomes the criterion by which the two generations are to be distinguished." He says:

I venture to think it premature to rush into inductive reasoning from imperfectly established premises. The case of *Fucus* in which the *Fucus* plant is shown to have the full number of chromosomes goes dead against the idea that the sexual generation (and who could call a *Fucus* plant anything but sexual) necessarily has the reduced

number of chromosomes. This fact is indeed a rebuff to deductive morphology.

When, however, Strasburger (1906) and Yamanouchi (1909) followed out the logical trend of the chromosome evidence unreservedly, this life history of *Fucus* became more readily comparable with that of the cormophytes and with those of certain brown and red algae that had in the meantime been elucidated by Williams and Yamanouchi. From this point of view, elaborated by Yamanouchi, the *Fucus* plant with its $2X$ number of chromosomes is a sporophyte and the reproductive organs arising in its conceptacles are sporangia comparable with those of a seed plant. After the reduction, which occurs at the normal point, at *sporogenesis*, each of the four megaspores, without escaping, gives rise to a gametophyte of two fertile cells or eggs. Each of the four microspores in turn forms a gametophyte, or X generation, of but sixteen cells, each of which is fertile and forms a spermatozoid. It is interesting to note here the similarity which has been pointed out by Strasburger and by Chamberlain of the chromosome cycle of *Fucus* to that of animals. In the latter, from the plant cytologist's point of view, the sexual generation has become reduced to the four haploid nuclei formed at spermatogenesis and oogenesis; and the so-called ovary and spermary are really spore-producing organs of the $2X$ or asexual generation.

In the brown seaweed *Dictyota* the discovery of the chromosome cycle revealed, for the first time in any thallophyte, an alternation that seemed clearly comparable with that of the cormophytes in this respect. Williams (1904) was able to show that the morphologically similar, mature plants of *Dictyota dichotoma* differ not only in that some produce spores only and others male or female reproductive cells

only, but also that the nuclei of the former have twice as many chromosomes as those of the sexual plants. He found also that the number of chromosomes is reduced at tetraspore formation and held that all this cytological evidence indicated the alternation of the sexual and the tetrasporic plants. The doubts of conservative botanists regarding the regular and necessary sequence of these haploid and diploid plants were dissipated when Hoyt (1910) raised fruiting tetrasporic plants from eggs and mature sexual plants from tetraspores. Hoyt thus demonstrated, for the first time by cultures in any alga, the identity of this alternation with that of the cormophytes. Yamanouchi (1911 and 1913) has demonstrated, cytologically and in part by cultures, the occurrence of an exactly similar type of alternation in the brown algæ *Cutleria* and *Zanardinia*, the life cycle of *Cutleria* seeming peculiarly like that of the cormophytes because the two generations differ not only in chromatin content, but also in structure.

In the red seaweeds also the use of cytological methods and the determination of chromosome numbers has given a series of very suggestive, though not as yet easily interpreted, results. Oltmanns (1898) showed that the nucleus of the carpospore is a direct descendant of the diploid oospore nucleus. Wolfe (1904) decided that in *Nemalion*, a species that does not form tetraspores, the reduction occurs at the budding out of the carpospores from the mass of cells arising by division of the fertilized egg. He therefore follows Oltmanns in regarding the diploid cell mass mentioned as the sporophyte of this species. In a series of red algæ, which have a tetrasporic phase in the life cycle, Yamanouchi (1906), Lewis (1909) and Svedelius (1911) have demonstrated, cytologically, an alternation of two generations very similar in

character to that first found in *Dictyota*. Lewis (1912) later proved conclusively by the use of cultures that the haploid sexual plants arise from tetraspores only, while the diploid fertilized egg gives rise, through the carpospores formed from it, to tetrasporic plants only.

In the interpretation of the phenomena seen in these red algæ Yamanouchi regards the tetrasporic plant as the more primitive phase of the 2X generation, and carpospore-formation as a sort of secondarily developed polyembryony for multiplying the progeny from each fertilization. Lewis's view, on the contrary, holds that the tetrasporic plant is, in origin, an early, self-propagative phase of the primitive, haploid, sexual generation. Further he suggests that, in accordance with a general tendency evident in many sexual plants, the process of reduction has here been postponed, and pushed forward from the time of carpospore-formation, where it still occurs in the primitive form *Nemalion*, into this originally haploid tetrasporic plant.

Though no generally accepted interpretation has yet appeared of the somewhat varying chromosome cycles that have now been elucidated in green, brown and red algæ, yet the mass of facts thus far obtained presents an impressive picture of the essential identity of reproductive processes in these plants with those found in the cormophytes. Perhaps the most interesting point noted in making such a comparison is the fact that the type of life cycle among algæ that corresponds most closely with that of an archegoniate, *e. g.*, is the type found in several genera of the brown algæ. The fact may be recalled here also that it was to the gametangia of this group that Davis (1903) finally turned in his search for a prototype of sexual reproductive organs of the bryophytes.

VII. SEXUALITY, CHROMOSOME HISTORY AND ALTERNATION IN THE FUNGI, 1820-

In this group of parasitic or saprophytic thallophytes we shall find as great a variety in the type of reproductive process as in their mode of nutrition at the expense of the hosts beset by them. At the beginning of last century fungi were commonly supposed to arise spontaneously "out of the superfluous moisture of the earth and rotten wood."

Observations had been made long before this, it is true, sufficient to render improbable the spontaneous generation of the fungi then commonly believed in. Thus Micheli (1729) had raised a fungus mycelium from spores. Ehrenberg (1820) did the same and also saw the conjugation of *Sporodina*. Du Trochet (1834) proved that the mushroom arises from threads of the mycelium in the soil.

The spontaneous generation of even the simplest of these parasitic or saprophytic thallophytes—the bacteria—had been denied by Leewenhoek at the end of the seventeenth century. In one of his numerous letters to the Royal Society he denies the spontaneous origin of the animalculæ or bacteria which he found in the mouth. These he found present even in the mouths of ladies who clean their teeth carefully! He insists that these organisms are like those he had found in pools of water, and then goes on to say, in a paragraph that reads like a modern health commissioner's report:

Now when people wash their beer mugs and drinking cups in the water from ponds and streams, who can tell how many of these animalculæ may stick to the sides of the glass and thus get into the mouth.

The hazy or bizarre beliefs concerning the occurrence and the mode of reproduction in the fungi, current at the middle of last century, were dispelled by the studies of a group of able investigators

early in the second half of the century. First came the splendid work of the brothers Tulasne (1847-1854) on the smuts and rusts, and their discovery of the oogonium of *Peronospora*. Pringsheim in 1857 studied the sequence in development of the zoosporangia and oogonia of the water moulds. Then came the researches of that master mycologist, Anton de Bary, on the reproductive structures of *Peronospora* (1861), of *Pyronema* and *Sphaerotheca* (1863), and on the life histories of the rusts, 1853 and 1865. The results of his own work and that of his students Woronin and Janczewski convinced de Bary that, in the Ascomycetes, as well as in the phycomycetous *Peronosporas*, the contents of an oogonium is fertilized by the escape into it of the living contents of the antheridial tube that grows beside it.

In the seventies and eighties a vast number of detailed observations concerning reproductive processes in the fungi were accumulated by many observers, led especially by de Bary's student, Brefeld. One outcome of this work which concerns our particular problem, was the insistent, though unconvincing denial by Brefeld of the sexuality of the ascomycetes.

In the last decade of the nineteenth century, with the application of new methods of fixing, sectioning and staining, a new era opened in the study of sexuality in the fungi, an era in which American workers have played a prominent part from the beginning.

As early as 1886 Rosenvinge had succeeded in staining the many nuclei of the mycelial cells of toadstools, also the primary basidium nucleus, and the four spore nuclei arising from this.

Humphrey (1892) and Hartog (1895) followed the history of the nuclei in the antheridium and oogonium of *Saprolegnia*, by the use of stained sections, and con-

cluded, as de Bary had done, that there is no fertilization in these forms. Not until the work of Trow (1904) and Claussen (1908) was it proven that the antheridium of these water molds is sometimes functional, and not always vestigial as de Bary (1881) and Humphrey had thought.

The earliest cytological work on the ascomycetes, after the detection of their nuclei by Schmitz, was that of Dangeard (1894). He described and figured a fusion of two nuclei in the ascus of *Exoascus*, of *Peziza*, of the truffle and others. The source of the two fusing nuclei Dangeard did not trace back farther than the subterminal cell of a hooked hypha from which the ascus arises in *Peziza* and others. The ascus with its fusion nucleus he regarded as an oospore.

In 1895 there was announced from Strasburger's famous laboratory at Bonn a discovery which seemed at one stroke to settle the dispute between de Bary and Brefeld, and to definitely demonstrate the occurrence of a sexual nuclear fusion in the sexual organs seen by de Bary. In that year Harper showed that out of the opened antheridial tube of the hop mildew, *Sphaerotheca*, a male nucleus passes into the oogonium and fuses with its nucleus. The whole behavior of antheridium and oogonium and their contents had every aspect of a real sexual process, as de Bary had asserted in 1863. What made Harper's discovery still more significant was the determination of the fate of the fusion nucleus in relation to the nuclei of the ascus and spores. Harper found that one of the row of 5 or 6 cells resulting from the division of the fertilized oogonium has two nuclei. These two descendants of the diploid nucleus, formed at fertilization, afterward fuse, and the cell containing them swells to form the single ascus of this species. This, presumably tetraploid, fu-

sion nucleus of the ascus then grows and divides three times to give the eight spore nuclei. In the following year or two Harper (1896-97) demonstrated a sexual fusion of the same type at the initiation of the fruits of another mildew, *Erysibe*, and of the saucer fungus, *Ascobolus*. The numerous asci of these forms all arise from binucleate branches of the binucleate, subterminal cell of the fertilized oogonium. Each ascus is at first binucleate, but later, as had been seen by Dangeard (1894), the two fuse and then by division the eight spore nuclei are formed as in *Sphaerotheca*.

In the course of the following decade Harper reported the occurrence of two nuclear fusions, like those of *Sphaerotheca*, and at the same points in the life cycle, in the mildews *Erysibe* (1896) and *Phyllactinia* (1905), and in the saucer fungus *Pyronema* (1900). Moreover, he found in *Phyllactinia* a synopsis and evidences of a double reduction of the chromosome number in the divisions of the presumably tetraploid, fusion nucleus of the ascus. *Pyronema* proved interesting also in having multinucleate gametes, such as were at this time being studied by Stevens in the white rust, *Albugo*. Harper believed that many pairs of male and female nuclei fuse in the oogonium of *Pyronema*.

As the outcome of this whole series of studies by Harper it seemed clear that there is in many ascomycetes an alternation of a haploid generation, the vegetative mycelium, with a diploid generation, the fertilized oogonium and the ascus-forming hyphae arising from it. The second fusion, in the ascus, was regarded as a nutritive phenomenon to provide a nucleus adequate in size for the organization of the relatively huge ascus.

At the opening of the century the observations of a number of workers on the simpler ascomycetes, *e. g.*, by Juel (1902),

Barker (1902), seemed to establish the occurrence of a nuclear fusion in the oogonium in these forms also. This, with Harper's, work made it seem probable that this fusion is a frequent phenomenon throughout the ascomycetes in general.

The researches of certain other cytological workers, however, convinced them that no fusion of nuclei really occurs in the oogonium of the ascomycetes studied by them. Thus Dangeard (1897 and 1907), working on *Sphaerotheca* and *Erysibe*, found no fusion except that in the ascus. Claussen (1907) and Brown (1909) could find no other in the varieties of *Pyronema* studied by them. Both workers find paired nuclei associated in the ascogenous hyphae and finally in the young ascus. Claussen, therefore, regards the fusion in the young ascus as a fusion of descendants of the sexual nuclei that were brought together in the oogonium but did not fuse there. In other words, he thinks it a real sexual fusion which has been deferred. Brown, on the other hand, says that in his plant no antheridial nuclei are concerned, since the antheridium never reaches the oogonium. He therefore regards the fusion of pairs of nuclei, derived from the oogonium, which occurs in the ascus, as one that serves as a substitute for the sexual fusion that primitively occurred in the oogonium. Brown's view is supported further by his work on *Lachnea* (1911), and by Faull's recent work (1912) on certain *Laboulbenias*.

If this view of Brown's be accepted it implies that the original diploid condition of the cells of the sporophyte has been altogether eliminated, except for the brief uninucleate stage of the ascus. In spite of this, however, the whole structure and development of the original 2X generation, from fertilized oogonium to mature fruit and ascus, has been retained. This same normal type of vegetative structure, in spite of an ab-

normal chromosome number, has been demonstrated in gametophyte and sporophyte of aposporous and apogamous mosses and ferns. It is implied also in Lewis's suggestion that, in the red seaweeds, the reduction has been postponed from its original location at carpospore-formation over into the primitively haploid tetrasporic phase of the next generation.

Still other recent work on the ascomycetes, however, supports Harper's view that a double fusion frequently occurs in the ascomycetes. Thus Blackman and Fraser (1906), Fraser (1907-08) and Fraser and Brooks (1909), find evidence of several degrees of loss of function of the antheridia in the different species of the cup fungi *Lachnea* and *Humaria*. In those cases where no antheridial nuclei are discharged into the oogonium, nuclei of this organ itself are believed, by these workers, to fuse in pairs within it. The later fusion in the ascus, which they find in common with all workers, they regard as a nutritive phenomenon.

Until toward the end of last century the basidiomycetes were generally assumed not to be sexual. At least no sexual organs had been described for them, with the exception of the spermatogonia and aecidia of the plant rusts. These had been called male and female organs, respectively, by Meyen, before the middle of the century. The very first nuclear studies of the rusts and toadstools, however, revealed the occurrence of a nuclear fusion, and at another point in the life history, indications of the complementary process, a reduction, were discovered.

In the case of the rusts Rosen (1892) saw two nuclei in the aecidiospore of certain species. Dangeard and Sapin-Trouffy (1893) reported the occurrence of a nuclear fusion in the teleutospore. Sapin-Trouffy (1896) found that the cells of the aecidium-bearing mycelium are uninucleate up to the

very base of the chain of aëdiospores. Maire (1900) first stated clearly the whole nuclear cycle in rusts: Beginning with the binucleate aëdiospore there follows, in the wheat rust, *e. g.*, the uredo, or rust stage which has a binucleate mycelium and forms binucleate uredospores for several generations. The two nuclei of the young teleutospore, finally formed on this mycelium, fuse as the spore matures. The two divisions of this fusion nucleus in the promycelium give rise to the four nuclei of the four sporidia which germinate to the uninucleate cluster cup mycelium on the barberry. Maire saw in this life history a real alternation of generations, the gametophyte or *X* generation beginning with the sporidium, the sporophyte or *2X* generation, with the mother cell of the aëdiospore chain.

Blackman (1904) and Christman (1905) discovered the origin of the binucleate condition of this mother-cell in species of *Phragmidium*. It there arises by the migration of a nucleus from one cell into another, or by the fusion of the cytoplasm of two cells to form the mother-cell of the spore chain. The two nuclei thus brought together divide simultaneously or conjugately, each contributing a nucleus to the first and to each succeeding spore. This conjugate division of the paired nuclei and their descendants was shown to occur all through the uredo generation up to the formation of the young teleutospore. In the interpretation of their discoveries Blackman and Christman differ more widely than in the facts reported. The former reasserts the surmise of Meyen and believes the basal cells of the spore chain are oogonia which were primitively fertilized by the now functionless spermatia, or pycnospores, produced in separate organs on the barberry leaf. Christman, on the contrary, regards the fusing cells at the base of the aëdium as the primitive, un-

differentiated sexual organs of these fungi. He holds that male and female organs have never become differentiated in this group, and thinks that the spermatia are, or were, propagative cells of the *X* generation.

The observations of many workers on the smuts and on the toadstools have shown the frequent occurrence in them of an association of nuclei and the final fusion of two nuclei in the chlamydospore or the basidium. The time and mode of association of the fusing nuclei, or of their progenitors, are very different in different forms. The fusion, and what appears to be the reduction divisions are, however, constant in location in each species, and are always closely associated. Thus, *e. g.*, the nuclear fusion in the smuts often occurs in the chlamydospore, according to Dangeard (1893) and Rawitscher (1912), and reduction evidently follows immediately in the next developmental phase, when this spore germinates to form the sporidia. In the toadstools, according to Wager (1893), Dangeard (1894), Harper (1902), Nichols (1904) and Levine (1913), the fusion of nuclei occurs in the basidium, and the reduction at the very next division of this fusion product, when the four spore nuclei are formed.

The striking uniformity with which the apparent reduction occurs in all basidiomycetes, at the time of formation of the sporidia or basidiospores, affords good evidence that this type of spore-formation is a long-established one, common to the whole group. It thus supports Brefeld's view that the promycelium of the smuts and rusts is homologous with the basidium of the higher forms. That the point in the life cycle where the associated nuclei finally fuse is the point at which it occurred in the earliest basidiomycetes, is not so clear. The modes of bringing about the first association of the paired nuclei are so varied that

it is difficult to detect any clearly ancestral type among them all. The structures concerned with this process in the æcidium-forming rusts certainly seem most readily comparable with the reproductive organs of other thallophytes. It seems probable that the occurrence of fusion at the same point in all forms is due to its being postponed in all forms, as long as it could be without being pushed over into another phase of the life cycle.

It would be instructive to spend another half hour, as we can not do here, in considering those peculiar short cuts in reproduction known as apogamy and apospory. These phenomena are so patently secondary, and so relatively infrequent, that they can not be looked to for evidence of fundamental importance concerning the history or the significance of the essential sexual process itself. Their study has, however, served to correct certain false assumptions concerning the relation between the difference in chromosome number, and the difference in structure, of the two generations. For example, the apogamous production, by *Nephrodium molle*, of a normal fern sporophyte with the $2X$ number of chromosomes, demonstrates, as no other kind of evidence could, that de Vries was right in regarding the normal sporophyte as really two beings in one. Incidentally too, such phenomena suggest how comparatively unimportant it is, for the structure of the plant, in what manner, and at what point in the life history, the association of the $2X$ number of chromosomes is brought about.

CONCLUSION

In our rapid glance at the progress made in the study of this problem, during twenty centuries, we have seen how for eighteen centuries men attempted to solve the problem by recourse to philosophical reasoning, without the aid of detailed observation or

experiment. Then, in less than two centuries, by the use of these means, Camerarius proved that pollination is a necessary condition of seed-formation; Koelreuter demonstrated that characters from both parents appear in hybrid offspring; Amici, Schmitz and Strasburger showed how the mingling of parental qualities is made possible by the approximation and fusion of parental protoplasts and nuclei.

The sexuality which was first suspected, and first experimentally proven, in the seed-plants, has now been demonstrated in all groups of plants save the bacteria and their allies. The primary feature of the process, the union of two parental nuclei, is the same in all. The method of bringing together the two nuclei varies widely, this variation sometimes involving even the complete disappearance of externally recognizable sexual organs. During the evolution of plants old methods of accomplishing the approximation of the nuclei have been discarded, and new methods have arisen. In the latter case a fusion of nuclei of closer kinship has often been substituted for the primitive one of more distantly related nuclei. This seems evidently the case, for example in the apogamous ascomycetes, perhaps also in the basidiomycetes, and surely so in the cases of nuclear fusion in the prothallia and in the sporangia of apogamous ferns.

In the process of fertilization, as we understand it at present, there are brought together two distinct sets of chromosomes, which in the nuclear divisions of the sporophyte, or $2X$ generation, are often found associated in pairs. The exact manner in which these chromosomes become paired, and the possibility of their attaining any more intimate association, either in the resting reticulum or in synapsis, are not yet definitely determined. If, as is indicated by Mendelian phenomena, and as is demon-

strated cytologically to the satisfaction of many workers, there is no loss of identity of the chromosomes in the sporophyte, then there is no very significant fusion at any point in the life cycle in consequence of the sexual process. Members of the two sets of chromosomes may be interchanged or shuffled, probably at synapsis, and thus new sets or combinations be formed in the haploid nuclei at reduction. These new combinations, however, are still made up of the same discrete individual chromosomes.

The essence of the sexual process then, as far as yet morphologically demonstrated, consists not of a real fusion, but merely of a temporary association, followed by a re-assortment at sporogenesis, of those ultimate, inheritance-bearing units—the chromosomes.

DE. J. J. RIVERS

WITH the death of this aged naturalist in southern California last December, one of the last links joining the present with the beginning of modern science has been broken. Born in England in the early twenties of the last

century, his childhood days were those of Murchison and Lyell, the years of his young manhood those of Darwin, Dana and Hall, while Hugh Miller, Huxley and Tyndall were his contemporaries. His place in middle-class English life and the possession of private means made it unnecessary for him to devote himself to the practise of his profession, and his interest in the awakened spirit of research kept him busy in the fields of discovery during the half century of his life in England. His first contribution to science was a paper read before a society in Birmingham in 1840. The writer has in manuscript one of his lectures read before a similar body in London in 1863, with the names of Stafford, Hardin, Fay, Spence-Bate, Hodges and Scrivener, in the discussion on the evidences of the antiquity of man, in which he places this age conservatively at 100,000 years. This epitome of results attained a half century ago gives sufficient data to indicate his place in the thought of his time.

He was preeminently an entomologist, adding several new species to British Lepidoptera and Coleoptera. In this pursuit he was in personal touch with Darwin. He came to this country in 1868 and after a few years went to the Pacific coast. Here the Le Contes found him, and by their influence he was made curator of the museum in the University of California. While in this service it was said of him that his ability was sufficient for any office in the institution, even for its presidency. Under his guidance was trained a group of young students who have since won an honorable place as men of science.

He resigned when past seventy, and for twenty years was the Hugh Miller of the California coast, gathering insects and fossils all the way from San Diego to Santa Barbara. His collection of insects was purchased about ten years ago for the German Royal Museum in Berlin. His collection of Cenozoic marine fossils of over 200,000 specimens, classified by himself, was purchased for Beloit and Pomona Colleges, and forms an invaluable part of their illustrative material.

He lived his own life, neither seeking nor shunning publicity. To the world he was only

a gray old man; to those whom he knew and cared for, the most delightful companion. He added about a score of species of insects and mollusks to the world of knowledge and something like the same number have received the name *riversii* in his honor. Without relatives, in an alien land, his life went out amid a small circle of very dear friends.

IRA M. BUELL

LOGAN MUSEUM, BELOIT COLLEGE,
BELOIT, WISCONSIN

THE FOURTH INTERNATIONAL BOTANICAL CONGRESS, LONDON, 1915

THE second circular for the Fourth International Botanical Congress to be held at London, 1915, has been just received. As the time when motions and resolutions must be ready is short the circular is reprinted below entire, excepting that only the American members of the committees are mentioned.

The Nomenclature Section of the Third International Botanical Congress, held at Brussels in 1910, carried towards completion the work of the Vienna Congress (1905) on the international rules governing questions of nomenclature. The combined result of the decisions reached at Vienna and Brussels has been published in the second edition of the "Rules of Botanical Nomenclature." There remain, however, certain points which have to be settled by the Nomenclature Section of the London Congress in 1915.

The program of work for 1915 was defined by the Congress of 1910 as follows:

1. To fix the starting-point for the nomenclature of

- (a) Schizomycetes (Bacteria);
- (b) Schizophyceæ (excepting Nostocaceæ);
- (c) Flagellatæ;
- (d) Bacillariaceæ (Diatomaceæ).

2. To compile lists of nomina generica utique conservanda for

- (a) Schizomycetes;
- (b) Algæ (incl. Schizophyceæ, Flagellatæ, etc.); new lists for groups not included in the list of 1910 and also a supplementary list;
- (c) Fungi;
- (d) Lichens;
- (e) Bryophyta.

3. Compilation of a double list of nomina gener-

ica utique conservanda for the use of paleobotanists.

4. Discussion of motions relating to new points which were not settled by the rules adopted at Vienna in 1905 and at Brussels in 1910.

The carrying out of this work has been entrusted to two committees under the direction of a rapporteur général, Dr. J. Briquet (Geneva), assisted by a vice-rapporteur, Professor H. Harms (Berlin). In the compilation of the lists of nomina conservanda, the rapporteur général will have the assistance of a certain number of editors in each committee. On these several committees the following names of American botanists are found:

Dr. A. Evans, New Haven, Conn., U. S. A. (Hepaticae).

Professor A. J. Grout, 360 Lenox Road, Brooklyn, N. Y., U. S. A. (Mosses).

Dr. J. C. Arthur, Purdue University, Lafayette, Ind., U. S. A. (Fungi).

Professor G. F. Atkinson, Cornell University, Ithaca, N. Y., U. S. A. (Fungi).

Professor W. G. Farlow, Harvard University, Cambridge, Mass., U. S. A. (Fungi).

Dr. R. Thaxter, Harvard University, Cambridge, Mass., U. S. A. (Fungi).

F. S. Collins, 97 Dexter St., Malden, Mass., U. S. A. (Algæ).

Dr. F. H. Knowlton, U. S. National Museum, Washington, D. C., U. S. A. (Paleobotany).

Ch. D. White, U. S. National Museum, Washington, D. C., U. S. A. (Paleobotany).

The circular further explains as follows:

The functions and program of work of these committees are as follows:

1. The Rules of Nomenclature adopted at Vienna in 1905 and at Brussels in 1910 remain in force. Additions may be made to the present code only: (1) in the form of rules bearing on new points not covered by the decisions of 1905 and 1910; (2) in the compilation of supplementary lists of nomina generica utique conservanda, and in fixing the starting-point for the nomenclature of special groups, as stated above.

2. All motions must be presented in the form of additional articles to the rules of 1905-1910, drawn up in French in the form adopted in the International Code now in use. Lists of nomina generica must be drawn up in conformity with the scheme adopted in the "Rules," edition 2.

3. Motions must be drafted as briefly as possible in Latin, French, German, English or Italian. So

far as possible, statistics should be supplied, indicating the consequences of the proposed motions.

4. At least sixty printed copies of the motion with the grounds of support must be sent to the rapporteur général before April 30, 1914.

5. Motions will be communicated by the rapporteur général to the members of the committees as they arrive. The members of the committees who were nominated at Brussels in 1910 are regarded as having accepted nomination, unless they have expressly signified the contrary to the rapporteur. Committees may, in case of necessity, co-opt new members who are specially competent.

6. The rapporteur général will draw up, after May 31, 1914, a critical and classified résumé of the motions which have been submitted and of the lists compiled by the special editors. He will submit this résumé to each member of the committees, and will draft on the basis of the collected motions a supplement to the Rules of Nomenclature. The work of the committees and of the rapporteur will be completed by November 30, 1914.

7. This supplement to the "Rules" will be sent out before January 1, 1915, to the principal botanical societies, and to the important botanical institutions in the different countries, and also to the principal periodicals, particularly those which specialize in cryptogamic botany and paleobotany.

8. Motions which reach the rapporteur after April 30, 1914, can be submitted to the Nomenclature Section of the Congress, only on condition that at least one hundred printed copies are sent to the president of the Section before the opening of the discussion, and that a majority of two thirds of those voting is in favor of their acceptance. New motions presented during the discussion can be admitted only if a majority of two thirds of those voting is in favor of their acceptance, and will not be voted upon until the next day.

9. The rapporteur will preserve all the documents which have been used in the elaboration of the proposed supplement to the "Rules of Nomenclature." These documents will be available for the use of the Congressists in London.

10. The revision of the Rules of Nomenclature has already occupied three congresses, namely, at Paris, Vienna and Brussels, and by 1915 the rapporteur général will have followed their details for fifteen years. It is highly desirable from all points of view, that this work should be completed in London in 1915, and should cease to occupy the International Botanical Congresses. We, therefore, urgently beg botanists in general, and cryptogamists and paleobotanists in particular, to examine

carefully these points which still require consideration, and to formulate their propositions in such a manner that nothing may be left over for 1920.

11. A later circular will supply detailed information on the internal organization of the Nomenclature Section of the Congress so far as concerns the nomination of delegates, the discussion of motions, and the propositions of the Committees; also on the method of voting.

American botanists should remember the following addresses:

Dr. J. Briquet, Botanical Garden, Geneva, Switzerland—rapporteur général.

Dr. A. B. Rendle, British Museum (Nat. His.), London, Eng.—general secretary.

THE AMERICAN SOCIETY OF NATURALISTS

MEMBERS of the American Society of Naturalists, in common with other scientific societies, have been invited by the organizing committee of the Nineteenth International Congress of Americanists to participate to the fullest extent possible in the important session to be held by the Congress in Washington October 5-10, 1914.

Following the meetings there will be a very instructive trip, including visits to the museums of Philadelphia, New York, Brooklyn and Cambridge, to the museum and mounds at Columbus, Ohio, and to the museums of Chicago and Davenport; and finally there will be an extension of the trip to Denver, Santa Fé, and certain cliff-dwelling as well as other archeological remains of Colorado and New Mexico, terminating with a pre-arranged visit of scientific interest to the living Pueblo Indians.

Requests for further information and applications for membership in the Congress should be addressed to the secretary of the Congress, Dr. A. Hrdlička, United States National Museum, Washington.

BRADLEY M. DAVIS,
Secretary

SCIENTIFIC NOTES AND NEWS

THE present issue of SCIENCE is the thousandth number of the new series.

DR. HERMANN M. BIGGS was the guest of honor at a dinner given by two hundred of his professional colleagues in New York on February 7. Among the speakers were Professor William H. Welch of Johns Hopkins University, Dr. William H. Park, Mr. Robert W. De Forest and Borough President Marks.

At the commemoration day exercises of the Johns Hopkins University, a portrait was presented of Dr. Edward H. Griffin, professor of philosophy, to mark the twenty-fifth anniversary of his professorship.

THE Rumford Committee of the American Academy has made the following appropriations: To Alpheus W. Smith, of Ohio State University, \$100 for his research on the Hall and Nernst effects in the rare metals; to Charles G. Abbot, of the Smithsonian Institution, \$150 for his research on the application of solar heat to domestic purposes.

PROFESSOR WALLACE W. ATWOOD, formerly of the University of Chicago, has taken up his new work at Harvard University. His address will now be Harvard University, care of University Museum, Cambridge, Mass.

PROFESSOR A. N. TALBOT, in charge of theoretical and applied mechanics at the University of Illinois, has been appointed chairman of the joint committee on stresses in railway track and subgrade of the American Society of Civil Engineers and the American Railway Engineering Association.

DR. M. G. DONK, of the bureau of chemistry, has been detailed by the department of agriculture to cooperate with the department of forestry at the University of Idaho in investigations looking to better methods of utilizing mill waste and refining by-products obtained from stumps. The work will be a continuation and extension of experiments which have been carried on for the past three years by Dr. C. H. Shattuck, head of the department of forestry at Moscow.

SIR FRANCIS DARWIN delivered the first Galton anniversary lecture on February 16. The subject of the lecture was Francis Galton.

In the latter part of January, Dr. Arthur L. Day, director of the geophysical laboratory of

the Carnegie Institution of Washington, gave a course of five lectures before the graduate students of the geological department of the University of Chicago, on the genesis of minerals, eutectics and the volcanic gases of Kilauea. These were followed by a course of six lectures by Dr. John Johnston, of the same institution, on the chemical and physical effects of pressure and their bearing on certain geological problems. Both courses were also attended by the graduate students of allied scientific departments and by members of the staff.

DR. SHOSUKE SATO, of the Imperial University of Sapporo, Japan, will give a series of lectures at the University of Illinois, April 13 to 25. The general subject is "Fifty Years' Progress in Japan."

ON February 11, Mr. E. J. Mehren, editor of *The Engineering Record*, delivered a lecture before the college of engineering of the University of Illinois on "The Making of a Technical Journal." Mr. Mehren graduated from the University of Illinois in Civil Engineering in 1906.

PROFESSOR ARTHUR H. BLANCHARD, of Columbia University, on February 14 delivered illustrated lectures at the University of West Virginia on the subjects: "Park Boulevards," "Bituminous Surfaces and Bituminous Pavements," "Wood Block and Stone Block Pavements" and "Modern Developments in Highway Engineering in Europe."

Two years' salary, amounting to \$5,570, was voted by the United States Senate on February 12, to the widow of Dr. Thomas W. McClintock, of the United States Public Health Service, who died from spotted fever contracted while he was making researches into the cause and cure of the disease.

We learn from *Nature* that it has been decided to prepare for publication a biography of the late Sir William H. White, K.C.B., the eminent naval constructor. Mr. J. B. Capper, to whom the work has been entrusted, will be grateful for any material in the shape either of correspondence or of reminiscence throw-

ing light upon Sir William White's personality or work. Letters will be carefully preserved, copied and returned. Communications of all kinds should be addressed to Mr. Capper, care of Sir Henry Trueman Wood, secretary of the Royal Society of Arts, John Street, Adelphi, London, W.C.

DR. ROBERT KENNEDY DUNCAN, director of the Mellon Institute for Industrial Research of the University of Pittsburgh, died on February 18, in his forty-sixth year.

PROFESSOR WILLIAM WHITMAN BAILEY, professor emeritus of botany at Brown University, died at Providence on February 20, aged seventy-one years.

DR. ARTHUR HENRY PIERCE, professor of psychology at Smith College, died at Northampton on February 20, aged forty-four years.

DR. LAZARUS SCHÖNEY, a surgeon and scientific author, died at Coney Island, New York, on February 18, aged seventy-six years.

DR. R. T. ORMOND, known for his work in meteorology, died at Edinburgh on January 27.

THE sixth semi-annual meeting of the American Institute of Chemical Engineers will be held at Troy, N. Y., June 17-20, 1914.

OWING to the agitation to prevent the success of the International Congress of Ophthalmology to be held in St. Petersburg, Russia, on account of the exclusion of some and the restrictions imposed on other Jewish members, the following announcement was made early in January by Professor Bellarmino, the head of the congress at St. Petersburg: "The minister of the interior has granted, without exception, unhindered entrance into the empire and unlimited stay to all members of the Twelfth International Congress of Ophthalmology."

THE program for the twenty-eighth year of the botanical seminar of the University of Nebraska has been issued, giving the papers which will be presented before some twenty meetings that will be held in the course of the year.

WE learn from the *British Medical Journal*

that the oldest medical school in Australia, that of the University of Melbourne, will celebrate its jubilee this year. Work actually commenced in 1861, but its original buildings were not opened till two years later. The roll of medical graduates already numbers about 1,100, and over 380 medical students are now attending full courses of instruction. The Melbourne School has from the first insisted on a five years' course, and its degrees have been registrable in the United Kingdom since 1890. The celebrations will commence on Thursday, April 30, and will last three days. The university is asking the state government to provide funds for the appointment of assistant professors of anatomy, physiology and pathology, the proper staffing of these departments being regarded by the faculty of medicine as the most pressing want of the school. Old graduates are being invited to contribute varying sums annually for five years to a permanent fund, the interest of which will be devoted to the promotion of clinical research in the teaching hospitals of Melbourne. A history of the medical school is being prepared. The jubilee celebrations will include an inaugural ceremony in the Wilson Hall of the university; a series of short addresses on the history, needs and prospects of the school; demonstrations in the laboratories, museums and hospitals; a jubilee dinner, and a theater party. A portrait of the dean of the faculty, Sir H. B. Allen, is to be painted for presentation to the university.

THE conclusions reached as a result of six years' exploration in the Yukon-Tanana region, Alaska, by L. M. Prindle, have been published by the United States Geological Survey in Bulletin 525. It has been found that the placer-gold reserves of the Fairbanks district, even if only those deposits that can be mined by methods now in use are considered, are still very large. There are, however, still larger deposits of auriferous gravels whose content of gold is so small that they can be profitably handled only by improved methods of mining. These facts and the existence within the district of extensive alluvial deposits, which have not been thoroughly prospected,

make the outlook for placer mining in the region exceedingly hopeful. It is therefore by no means certain that the placer-mining industry will continue to decline as it has declined in the last two years. A large expansion of the industry in this field can be brought about only by lessening the operating costs through improved means of communication. As compared with alluvial mining, the lode-mining operations have been insignificant and have yielded no great body of facts upon which to base conclusions as to the persistence of the lodes. The facts presented in the report, however, show that the geologic conditions on the whole appear to be favorable to the occurrence of lode deposits and that these are not limited to the localities near Fairbanks which have been prospected.

THE International Conference on the Safety of Life at Sea, first suggested by the German emperor and convened by the British government, has now held its final meeting. We learn from *Nature* that as a result of its labors, a very important convention has been signed by plenipotentiaries of the following states: The British Empire, including Australia, Canada and New Zealand, which were represented separately, Germany, France, the United States, Austria-Hungary, Italy, Spain, Sweden, Norway, Holland, Belgium and Denmark. The text of the convention has not yet been published, but the chairman of the conference, Lord Mersey, has outlined its principal points in a speech moving its acceptance by the delegates. The convention must be ratified by the different states prior to December 31, 1914, and comes into force on July 1, 1915. An international service is to be established and placed under the control of the United States for the purpose of ice patrol and observation and for the destruction of derelicts in the North Atlantic. The masters of all vessels are to cooperate with this service. Safety of construction has been dealt with under the headings of "New vessels," and "Existing vessels." The convention provides that the degree of safety shall increase in a regular and continuous manner with the length of the vessel, and that vessels shall be as effi-

ciently subdivided as is possible having regard to the nature of the services for which they are intended. The convention provides that all merchant vessels of the contracting states when engaged upon international (including colonial) voyages, whether steamers or sailing vessels, and whether they carry passengers or not, must be equipped with wireless telegraphy apparatus if they have on board fifty persons or more (except where the number is exceptionally and temporarily increased to fifty or more owing to causes beyond the master's control). There are certain exemptions to this regulation. A continuous watch for wireless telegraphy purposes is to be kept by all vessels required to be fitted with wireless apparatus, as soon as the government of the state to which the vessels belong is satisfied that such watch will be useful for the purpose of saving life at sea. Meanwhile certain classes of vessels are specified as being required to maintain a continuous watch. The wireless installations must have a range of at least 100 miles. A transition period is provided to enable wireless apparatus to be fitted and operators and watchers obtained. The convention lays it down that there must be accommodation in lifeboats or their equivalents for all persons on board, and that as large a number as possible of the boats and rafts must be capable of being launched on either side of the ship, so that as few as possible need be launched on the weatherside. The convention specifies a minimum number of members of the crew competent to handle the boats and rafts. All ships are to have an adequate system of lighting, so that in an emergency the passengers may easily find their way to the exits from the interior of the ship. Ships of the contracting states which comply with the requirements of the convention are to have furnished to them certificates of the fact, which are to be accepted by all the states as having the same value as the certificates issued by them to their own ships.

UNIVERSITY AND EDUCATIONAL NEWS

LEHIGH UNIVERSITY will receive about \$800,000 under an adjudication of the eleventh ac-

count of the executors and trustees of the estate of Asa M. Packer.

THE Mask and Wig Club of the University of Pennsylvania has completed plans for the erection of a residence, to be presented to the university for the use of the provost. The building will cost between \$75,000 and \$100,000.

MISS EMILY MATILDA EASTON has by her will made a number of public bequests including £10,000 to the College of Medicine of the University of Durham and £5,000 to Armstrong.

SIR WILLIAM MACDONALD, of Montreal, has been elected chancellor of McGill University, in succession to the late Lord Strathcona.

DR. FORCHHEIM, professor in the Graz Technological School, has accepted the commission to organize a technical school at Constantinople.

THE following appointments for the faculty of George Peabody College for Teachers, the new Teachers College of the South, have been announced: Carter Alexander, Ph.D., professor of school administration (formerly assistant professor of educational administration, University of Missouri); Lula O. Andrews, A.M., assistant professor of English (formerly professor of English language, State Normal School, Farmville, Va.); John Lee Coulter, Ph.D., professor of rural economics (at present with the United States Census Bureau); Kary C. Davis, Ph.D., professor of agriculture (formerly professor of agronomy and principal of agricultural short courses, of the State Agricultural College of New Jersey); Frederic B. Dresslar, Ph.D., professor of school architecture and hygiene (formerly special agent of the United States Bureau of Education); Charles E. Little, Ph.D., professor of the teaching of Latin (formerly professor of Latin in the old Peabody College); Robert W. Selvidge, A.M., professor of manual and industrial arts (formerly professor of manual arts at the University of Missouri); Edward K. Strong, Jr., Ph.D., professor of psychology and psychology of education (now in the department of psychology, Columbia Univer-

sity); William K. Tate, A.M., professor of rural education (now professor of elementary education, University of South Carolina).

DISCUSSION AND CORRESPONDENCE

GRADUATE WORK IN AMERICAN UNIVERSITIES

THE university registration statistics published by Professor Tombo in *SCIENCE*, January 23, 1914, allow, among other things, an interesting and instructive comparison of the amount of graduate work being done in the thirty universities tabulated. The number of non-professional graduate students may be taken to represent the amount of research that is being done in a university, for, in general, a university will attract non-professional graduate students in proportion to the activity in the graduate departments. The relative amount of emphasis laid on graduate work in each university can be seen at a glance in the table below, where the thirty universities in question are arranged in rank according to the ratio of non-professional graduates to undergraduates, *i. e.*, the number of graduates to every hundred undergraduates. The first column gives the ratio of graduates to undergraduates based on the figures given under "College, Men," "College, Women" and "Non-professional Graduate Schools" in Professor Tombo's table.¹ The second column gives the total enrollment listed under these three heads, corresponding presumably with the enrollment of purely academic students.

University	Ratio	Total Students
1. Johns Hopkins	123	397
2. Pennsylvania	107	1,504
3. Columbia	102	2,960

The ranking of the universities obviously does not correspond in every case with the amount of productive scholarship that is issuing from a university, but, as far as the enrollment figures are correct, it would seem to indicate the relative emphasis that is being put upon graduate work. A correlation of the totals as given in the second column with the ratios of the first column gives a coefficient of about .046, or practically no correlation at all. This might be interpreted to mean that the universities possessing enormous undergraduate departments do not as a rule show an increased activity in graduate work, such as the number of undergraduates should warrant, presuming, of course, that the ultimate ideal of a university is held to be productive scholarship.

RUDOLF PINTNER

OHIO STATE UNIVERSITY

THE CAUSE OF THE PECULIAR SOUND MADE BY NIGHTHAWKS WHEN VOLPLANING

ALL are familiar with the resonant sound made by the nighthawk as he cavorts through the air. It may be described as a guttural "woof."

It has been a contested point as to whether this sound was produced by the open mouth or the wings. As it occurs at the point where the bird swerves upward in his downward glide and at no other time, it is very evident that the mouth plays no part, otherwise the sound would occur at other times.

While on Mt. Constitution, Orcas Island, Washington, about five o'clock in the evening one summer, Mark Said and I were watching the nighthawks in their tortuous flight. Unexpectedly one of the nighthawks made its dip, with the accompanying "woof," but a few feet from Mr. Said.

According to his description the bird threw its wings far to the front at the end of his downward glide, so that the uppermost quill feathers were pointed exactly in the direction of his glide. Going at such headlong speed, these quill feathers when thrown edgewise to the air vibrated strongly, causing the "woof."

SEATTLE, WASH.

SCIENTIFIC BOOKS

Vorlesungen über Landwirthschaftliche Bakteriologie. By DR. F. LÖHNIS, Professor an der Universität Leipzig. Berlin, Verlag von Gebrüder Borntraeger, W. 35 Schöneberger Ufer 12a. 1913.

Agricultural bacteriology is gaining prominence in scientific and practical circles. The agriculturist realizes more and more that scientific investigations are of help to him and the demand on colleges for courses in agricultural topics is constantly increasing. However, text-books are still scarce. The series of lectures by Professor Löhnis is the outcome of a course of lectures in connection with a general course in agricultural bacteriology given by him in the University of Leipzig.

The ground is covered as thoroughly as modern knowledge permits. No one realizes more fully than the author how much work is needed to complete our really very meager knowledge in many agricultural branches. The reader must be impressed with the fact, frequently stated, that research is necessary and that authors do not agree in many instances.

The book is divided into two parts—a general part and a special part. The general part consists of fourteen lectures. The first lecture gives a general introduction to the significance and the problems of agricultural bacteriology and includes a historical review and a list of

some important books bearing on the subject. The shape, development and classification of microorganisms is covered in two lectures. The size of bacteria is admirably illustrated by diagrams showing the relation of the bacterial content of milk, butter and cheese to definite quantities of these substances. Such illustrations render the book exceptionally valuable, especially to students. Three lectures are devoted to conditions of existence and multiplication of microorganisms and two lectures to methods of cultivation and combating microorganisms.

Under the general head of "Products of Microorganisms" six lectures are united. The production of pigment, light and heat are discussed. The circulation of nitrogen, carbon, hydrogen and oxygen are given with considerable detail and illustrated in diagrammatic fashion. These complicated subjects are dealt with in masterly fashion, notwithstanding the fact that some facts are still poorly understood. Similarly, a lecture is given to the discussion of the decomposition and assimilation by bacteria of phosphorus compounds and the solution of carbonates and silicates. Mention is also made in this lecture of sulphur and iron bacteria. For the sake of completeness one lecture deals with pathogenic functions of microorganisms. It is hardly necessary to state that this extensive subject is treated briefly. However, the chief principles of virulence, infection, immunity, vaccination, serum therapy and chemo-therapy are ably dealt with.

The second "special" part commences with a lecture on the bacteriology of foods for cattle. Here the author forcefully shows the rôle played by microorganisms in the ripening and decomposing of foods. Many gaps in our knowledge are clearly pointed out.

Two interesting lectures give the student the most necessary knowledge of the milk question. The attitude of the author in regard to this important subject is of special interest. There are at present in this field the extreme views of those commercially interested and the no less extreme views of some sanitarians. Professor Löhnis takes an intermediate position, recognizing the necessity of

gradual, rather than forced, improvement in the milk supply, and sanitarians are warned against entertaining premature conclusions. Those sanitarians who have recklessly connected mastitis in cows with human diseases receive criticism from the author, although he does not neglect to emphasize that milk from cows with diseased udders should be rigorously excluded from human consumption, unless previously boiled. The author also points out that—as desirable as it is to establish grades of market milk—existing regulations are rarely reasonable and generally immature. Numbers of bacteria in milk are of relatively smaller significance than the possible presence of pathogenic bacteria. These may multiply in milk of small bacterial content more rapidly than in milk rich in bacterial life. Special emphasis is laid on the necessity of instructing producers. And here it must be stated that Professor Löhnis ranks among those old-world scientists who are ready to give full credit to American workers in agricultural fields.

One lecture is devoted to the bacteriology of butter and two lectures to cheese. There are five lectures on the bacteriology of manure and soil. These are also conservative and critical. Finally, the whole subject is reviewed in a retrospect and a prospect. Valuable suggestions for those interested in research work in agricultural lines are given.

As a whole the subject-matter is presented in good style, the numerous illustrations are exceptionally clear, and no one can read the book without adding materially to his knowledge and broadening his views.

P. G. HEINEMANN

Franz von Kobells Lehrbuch der Mineralogie. Seventh edition. By K. OEBBEKE and E. WEINSCHENK. Leipzig, Friedrich Brandstetter, 1913. Pp. viii + 405; 1 plate; 344 figures in text. Price, 8.50 Marks.

In 1899 the sixth edition of this popular German text-book on mineralogy appeared under the same joint authorship as the present edition. In the new edition the text has been increased by 67 pages. The general portion has been entirely rewritten and the descriptive

part revised so as to bring the mineral data up to date.

There are three subdivisions in the general part, namely: (1) Crystallography, (2) Physical Mineralogy, and (3) Chemical Mineralogy; the special part is devoted to Descriptive Mineralogy.

Crystallography is discussed in 70 pages and under three headings, (a) general morphological properties of minerals, (b) special geometrical properties of crystals and (c) twins, development and intergrowths of minerals and inclusions. The discussion of crystallography is well adapted to the needs of the beginning student. The more important classes of crystals are considered at length upon the modern basis of symmetry, but reference is also made to the rather useful ideas from the standpoint of pedagogy of holohedrim, hemihedrim and so forth. The crystal drawings are exceptionally clear. Fig. 51 is, however, inverted.

Thirty-seven pages are devoted to physical mineralogy, which includes the following subdivisions, (a) specific gravity, (b) elasticity and cohesion, (c) optical properties and (d) miscellaneous physical properties. The discussions in this section are again limited to only that which is of importance to the student who has a general knowledge of mineralogy in mind. Thus, the polarization phenomena of crystals are disposed of in 14 pages.

The next 60 pages are devoted to chemical mineralogy. Here, (a) general chemical properties, (b) occurrence and formation, (c) weathering and decomposition, (d) synthesis and (e) classification and nomenclature of minerals are discussed. The chapter on the occurrence and formation of minerals contains a large amount of information not usually included in text-books on mineralogy of this character. Brief reference is first made to the classification, form, structure and paragenesis of mineral deposits. Then follow concise descriptions of the various types of the more important rocks and mineral deposits. This chapter is very well written, and similar discussions could be introduced to advantage in American texts on mineralogy.

In the descriptive portion, extending over 215 pages, the classification of minerals according to elements is followed. The mineral descriptions are generally adequate, although native copper is disposed of in about one half page and with but four lines devoted to the Lake Superior occurrence. The statistics relating to the production of minerals are for 1910.

This edition of von Kobell's mineralogy of only 405 pages is much more comprehensive than any other text on the subject of similar compass. The authors are to be congratulated upon the clear and concise manner in which this wealth of material has been presented.

EDWARD H. KRAUS

MINERALOGICAL LABORATORY,
UNIVERSITY OF MICHIGAN

Outlines of Theoretical Chemistry. By FREDERICK H. GETMAN, Ph.D. John Wiley & Sons. 1913. Pp. ix + 467.

This book is written primarily for the use of students beginning the study of physical chemistry. It is always interesting to have the viewpoint of a new author in such an extended field as modern physical chemistry. The array of facts and theories in the recent literature of physical chemistry is so vast that necessarily each teacher must be content to select what he considers to be the most important principles and of need neglect others. Dr. Getman has chosen to chapter and classify nineteen lines of discussion. After discussing briefly the atomic theory and the periodic law, the conventional fields of physical chemistry are developed historically in most cases. This historical treatment is carefully handled for the most part, the tendency being throughout the book to treat the subjects considered from the viewpoint of the original investigators. While this treatment is excellent in most cases, a little more personality injected would clear certain points. For example, the chapter on Electrons can not give the student anything more than a very vague idea of the subject. On the other hand, the subjects of Thermochemistry, Equilibrium, Electromotive Force

and Actinochemistry are very clearly and satisfactorily handled.

The addition of a series of well-selected problems at the end of each chapter is to be highly commended.

While the press work of the book is of the same high quality as that of Wiley & Sons' text-books, it is to be regretted that the cost to the student is as much as \$3.50.

VICTOR LENHER

BOTANICAL NOTES

SMALL'S MANUALS

DR. J. K. SMALL, of the New York Botanical Garden, has been very industrious in the preparation of systematic manuals of botany as shown by his "Flora of the Southeastern United States," now in its second edition, his "Flora of Miami," "Florida Trees," both of which appeared during 1913, and now we have a "Flora of Lancaster County" (Penn.) in collaboration with the late J. E. Carter. The first-named books were noticed in these columns when they appeared, and it remains only to notice the last. While the Florida manuals dealt with a *terra incognita*, the Flora of Lancaster County deals with a region which "has been the scene of almost continuous botanical exploration and study for nearly a century and a half." In fact the work was begun by Muhlenberg in the latter part of the eighteenth century. Somewhat more than forty years ago Professor T. C. Porter published an enumeration of the indigenous and naturalized plants of the county, and this has formed "the basis of the present flora."

The book includes about 350 pages, and is an actual descriptive manual, and not a series of keys. In other words the treatment here reminds one of that in such a manual as Britton's, or Gray's, and while keys are freely used, the genera and the species are separately described. One wishes that more local floras could be modeled after this very satisfactory little book.

BOTANICAL NOTES

FROM the Central Experimental Farm at Ottawa, Canada, there comes a bulletin (No. 73) of more than ordinary scientific interest.

It is entitled "Smut Diseases of Cultivated Plants, Their Cause and Control," and was prepared by the Dominion Botanist, Mr. H. T. Güssow. In somewhat less than sixty pages the author presents in fairly non-technical language the important facts about smut fungi in general, followed by details regarding ten species which attack wheat, barley, oats, corn, broom corn, and millet. In an appendix the latter are described botanically for the benefit of students. Good figures, which are freely used, help both the farmer and the student to identify the diseased hosts, as well as the parasitic fungi. Preventive and remedial measures are suggested at every step. The importance of such a bulletin may be appreciated when we remember that it is estimated that Canadian farmers annually lose about \$15,000,000 from the ravages of these smuts.

BOTANISTS and foresters will be glad to know that Professor A. F. Blakeslee and his colleague, C. D. Jarvis, have reprinted the Keys to the Genera and Species of Trees in the Eastern United States. These were originally in their book "Trees in Winter," and the many requests from teachers and others for separate copies of these keys have induced the authors to issue them in a 15-page pamphlet. It may be obtained of the authors at Storrs, Conn., for 30 cents, and should prove helpful to teachers who are trying to teach their pupils how to know the names of the trees about them.

SOME months ago there came to hand the Annual Report of the Agrostologist and Botanist of the Transvaal for the year 1911, bearing date of June, 1912, but issued later from the press. It was prepared by Professor J. Burtt-Davy, the well-known botanist of south Africa, and contains many items of considerable botanical interest, especially to those whose interest extends to applied botany. A large part of the paper is devoted to a discussion of the plants suspected of being poisonous to cattle ("lamziekte").

AMONG recent contributions from the United States National Herbarium (Volumes 16 and

17) are the following: Cook and Doyle's *Stilt Palms (Iriartineae)*, describing three new genera; Britton and Rose's Studies in Cactaceae, in which they describe seven new species from Mexico, Guatemala and Panama; Cook's Relationship of *Pseudophoenix*, a curious relative of the Date Palm; Britton and Rose's Genus *Epiphyllum*, in which two new genera and five new species are described from Mexico and southward; Smith and Rose's Monograph of certain tribes (Hauyaeae and Gongylocarpeae) of the Onagraceae, represented by Mexican and Californian genera; Maxon's Fourth instalment of his Studies of Tropical American Ferns, containing notes on *Asplenium trichomanes*, *Dicksonia*, *Odontosoria*, and other fern genera, and new species of *Lycopodium*; Hitchcock's Mexican Grasses in the U. S. National Herbarium, including 133 genera and 613 species. The large genera are *Muhlenbergia* (58 species), *Panicum* (54 sp.), *Paspalum* (39 sp.), *Andropogon* (28 sp.), *Bouteloua* (28 sp.), *Sporobolus* (21 sp.), *Eragrostis* (21 sp.), *Aristida* (19 sp.) and *Stipa* (16 sp.). Six bamboos are enumerated.

The Contributions from the Gray Herbarium of Harvard University (N. S., XLII.) include critical studies of certain genera of Composites, and a report upon the grasses collected in British Honduras by Professor M. E. Peck.

CHARLES E. BESSEY

UNIVERSITY OF NEBRASKA

SPECIAL ARTICLES

MITOCHONDRIA IN TISSUE CULTURE

THE immense literature¹ which has grown up in the last few years, concerning these minute bodies found in the cytoplasm of various cells in many different species not only of vertebrate and invertebrate animals but also of plants, and the great importance which has been assigned to them by various authors must necessarily arouse even more general interest and increased observation and discussion.

A multiplicity of names has already been given these bodies: mitochondria and chon-

¹ J. Duesberg, *Ergebnisse der Anatomie und Entwicklungsgeschichte*, Bd. XX., 1911.

driomiten by Benda; chondriocenten, chondriosomen, chondrion and plastosomen by Meves; plasmafaden, plasmaköner by Retzius; paramiton or miton by Flemming; microsomen by Van Beneden; granule and filament by Altmann.

The mitochondrial theory has been most widely promulgated by Benda (1899-1903) and Meves (1907-1908). Duesberg states the theory concisely as follows: the mitochondria are specific elements of the cytoplasm, which arise from preformed elements in the male and female sex cells and are carried over into every cell at mitosis. These bodies differentiate into specific parts of the various adult tissues. While there are many authors whose observations tend to substantiate the mitochondrial theory, on the other hand just as many writers refuse to accept the mitochondrial theory in its entirety. Some give observations to show that the mitochondria are formed from nuclear material at certain periods of the cell's activity.² Others claim that they are fermentation products of the activity of the centriole,³ and still others state that the mitochondria are throughout entirely different elements whose identity have nothing in common.⁴

The tissues from chick embryos grown outside the body in media of known chemical constitution, which we have been studying during the past three years, with other problems in mind, have shown such beautiful mitochondria in both fixed and living specimens that we are led to believe this method offers a better opportunity for their study than any heretofore used.

Small pieces of tissue from a chick embryo, four to ten days old, suspended in a drop of Lock's solution containing 0.25 per cent. dextrose are placed on the sterile surface of a clean coverslip. The coverslip is then inverted over a hollow ground slide, sealed with vaseline, and incubated at 39° C.; growth usually appears at the end of 10-20 hours. Such preparations are studied on the warm stage

with the No. 2 Zeiss apochromatic and a No. 4, 6 or 8 ocular.

Janus green in strengths of .00001 and .000005 of 1 per cent. stains the mitochondria in the living cells a brilliant blue green. The color fades, however, in from 15 minutes to 3 hours, and we have been unable to restrain. The janus green is also slightly toxic and kills the cells in a few hours. We are indebted to Dr. E. V. Cowdry for this particular janus green (di ethyl saffranin azo di methyl aniline) which was obtained by him from Dr. Bensley of Chicago. Attempts to stain with another make were unsuccessful.

Nilblew B. extra, for which we are indebted to Dr. Herbert Evans, was used in very dilute solution of .000005 to .0000025 of 1 per cent. for the detection of lipoids in connection with the mitochondria. It stains the lipoids pink, but is unfortunately somewhat toxic and, like the janus green, kills the cells in a few hours.

The preparations are fixed by placing the coverslip in a chamber of osmic acid vapor from two to five minutes and since the growth is very thin, the fixation is almost instantaneous and the mitochondria remains practically the same as in the living cells. The blackening caused by the osmic is bleached during the hardening processes by means of a few drops of hydrogen peroxide in the 70 per cent. alcohol and the preparations are then stained with Heidenhain's iron hematoxylin. Since in places the cells are flattened out on the under surface of the coverslip into a single layer much thinner than the usual thickness of a single cell, one can study the entire living cell and its contents with a minimal amount of focusing. Also at any moment during the observations the culture can be fixed and later the same cells studied in a stained preparation.

Mitochondria were studied in endothelium, mesenchyme, giant cells, ectoderm, heart muscle, smooth muscle and endoderm.

The stained preparations show great variety in the shape of mitochondria and often in the same specimen, as of heart muscle or mesenchyme, all the so-called types described by

² R. Hertwig and Goldsmith, 1909.

³ Vejdosky, 1907.

⁴ Veratti, 1909; Pensa, 1911; Linidegard, 1910; Curwitsch, 1910.

other observers are to be found. In such specimens, granules, rods, threads, loops and networks can be arranged in a continuous series; in other words, there are to be found in single stained preparations all gradations of size and shape from the small and large granules to short rods and long rods, to threads of varying length, to anastomosing threads and networks, which extend throughout the cytoplasm and to rings and loops of various shapes.

Certain kinds of cells do, however, contain characteristically shaped mitochondria. Intestinal or stomach endoderm shows only granules and short rods. Heart and smooth muscle cells contain in addition to the usual types large round and spindle-shaped mitochondria. In the heart muscle cell the appearance of the central body, probably the centrosome, at the base of the nucleus, is much more definite than in most cells. The mitochondria radiate out from this central body as though under the influence of the activity of the centrosome, as is believed by Vejdevsky.

By far the most important and interesting are the observations on the living cells. In the living cells the mitochondria are seen as slightly refractive opaque bodies. They can be studied from minute to minute over a period of several days if necessary. The mitochondria are almost never at rest, but are continually changing their position and also their shape. The changes in shape are truly remarkable not only in the great variety of forms, but also in the rapidity with which they change from one form to another. A single mitochondrion may bend back and forth with a somewhat undulatory movement or thicken at one end and thin out at the other with an appearance almost like that of pulsation, repeating this process many times. Again, a single mitochondrion sometimes twists and turns rapidly as though attached at one end, like the lashing of a flagellum, then suddenly moves off to another position in the cytoplasm as though some tension had been released. Corresponding to the forms observed in the stained preparations we find in the living that granules can be seen to fuse together

into rods or chains, and these to elongate into threads, which in turn anastomose with each other and may unite into a complicated network, which in turn may again break down into threads, rods, loops and rings.

The mitochondria in a cell of a living preparation of a piece of heart of a five-day chick embryo studied on the third day after the culture was made presented a very remarkable picture. Radiating out from the central body at the base of the nucleus were numerous granules, rods and thread-like mitochondria. They were seen to elongate to many times their original length, spreading out through the cytoplasm and to anastomose into a complicated network. About fifteen minutes later this network broke up and contracted into threads, rings, loops and rods and granules. This entire process took place without any noticeable change in the position or size of the cell.

The presence of fat is shown by the Nilblew vital stain within the varicose mitochondria. We have not observed any connection between the disappearance of mitochondria and the formation of fat within the cell as stated by Dubreuil.

The question as to whether the mitochondria divide, so that one half of each mitochondrion passes into each daughter cell at mitosis (Benda), is one of the most interesting in the whole field of work upon mitochondria. As yet we are unable to state definitely that such a division takes place. In the cells of the tissue cultures the behavior of the mitochondria is difficult to follow during mitosis, since the body of the cell contracts to much less than the normal size and its processes become exceedingly long and delicate. All of the mitochondria are drawn into the body of the cell and become very short dumb-bell-shaped granules during the late metaphase and anaphase. Owing to the very flat shape of the cells (growing along the coverslip) the spindle always appears horizontal to the coverslip and the plane of cleavage perpendicular to the surface. In some cells during the anaphase the mitochondria were observed to collect in a zone through which the cleavage plane will

later pass, and about equal parts of the mass of mitochondria were included in each daughter cell. In other cells no such definite behavior of the mitochondria takes place. They remain scattered throughout the cytoplasm or are collected at the two poles of the cell during the formation of the daughter cells.

The question of the behavior of the mitochondria during the life history of the cell is one of great interest and we feel confident that this method of study of the living cell will be of great value not only for making observations upon the mitochondria, but also for the study of other activities of the cell.

Can we infer from these observations anything concerning the real nature of the mitochondria? Are they organs of the cell, functioning in a definite manner, in other words a living part of a living cell? If they are organs of the cell, are they concerned in the routine metabolism which takes place in all living cells or are they concerned with the process of differentiation of such structures as the myofibrillæ, neuro-fibrillæ, white fibrous tissue, etc.? On the other hand, are we dealing with inactive metabolic products of the cell, inactive in the sense of not being a part of the living protoplasm? If so, are they excretory products which later are extruded from the cell or storage products which are being continually formed by the activity of the cell and again used up in its metabolism? What relation do they bear to the metabolism of the nucleus, if any? The discussion of these most important points must be left for a more complete account of the mitochondria in tissue cultures which is soon to follow.

W. H. LEWIS

JOHNS HOPKINS UNIVERSITY

ASTRONOMICAL AND ASTROPHYSICAL SOCIETY OF AMERICA

THE sixteenth meeting of the Astronomical and Astrophysical Society of America was held in Atlanta, Ga., in connection with the American Association for the Advancement of Science on December 29, 1913, to January 1, 1914. The general social features of this meeting participated in alike by the association and the affiliated societies

have already been described by the general secretary of the association.

In connection with the relation of this society to the association one matter may be mentioned. Following the adoption of the plan for large general quadrennial meetings the society voted to endeavor to meet with the association for these meetings.

The council elected the following persons to membership: The Rev. T. H. E. C. Espin, Tow Law, Co. Durham, England; Dr. C. C. Kiess, Laws Observatory, Columbia, Mo.; and to honorary membership, Professor G. F. J. Arthur Auwers, Bellevuestr. 55, Grosslichterfelde, Berlin, W., Germany.

The following members were in attendance: G. C. Comstock, W. S. Eichelberger, Philip Fox, C. H. Gingrich, C. S. Howe, W. J. Humphreys, F. R. Moulton, E. C. Pickering, W. F. Rigge, H. N. Russell, Frederick Slocum; and the following visitors from the association: William Bowie, S. M. Barton, E. B. Van Vleck, C. F. Emerson, and R. P. Stephens.

At the joint meeting with Section A of the association two admirable addresses were delivered. The retiring vice-president of the section, Professor E. B. Van Vleck, presented "The Influence of Fourier's Series upon the Development of Mathematics." The society was represented by Professor H. N. Russell, who spoke on "Relations between the Spectra and Other Characteristics of the Stars."

Aside from these two addresses the scientific program contained twenty-nine papers and a report from the committee on photographic astrometry. The titles are given below in the order of presentation.

"The Arlington Time Signals in Omaha," by W. F. Rigge.

"Astronomical Panoramic Views from a City Observatory," by W. F. Rigge.

"Micrometric Observations of the Holden and Küstner Double Stars," by Philip Fox.

"Note on the Present Spectra of Three of the Novæ," by W. S. Adams and F. G. Pease.

"Note on the Relative Intensity at Different Wave-lengths of the Spectra of Stars having Large and Small Proper Motions," by W. S. Adams.

"Memoir on the Theory of Orbits," by F. R. Moulton.

"Faint Standards of Photographic Magnitude for Selected Areas," by F. H. Seares.

"Temperature, Rainfall and Sunspot Records," by W. J. Humphreys.

"An Easy Method of Drawing the Normals to a Parabola from any Point," by S. G. Barton.

"A Graphical Solution of Cubic Equations," by S. G. Barton.

"The Color of Faint Stars," by F. H. Seares.

"The Moon's Mean Longitude, 1908 to 1913," by F. E. Ross.

"Proper Motion of Telescopic Stars," by G. C. Comstock.

"Errors in the Right Ascensions of Newcomb's Fundamental Catalogue," by W. S. Eichelberger and H. R. Morgan.

"Stellar Parallaxes with the 40-inch Refractor," by F. Slocum and S. A. Mitchell.

"The Objective of the Sproul Telescope," by J. A. Miller and R. W. Marriott.

"Wendell's Photometric Measurements," by E. C. Pickering.

"On the Cepheid Type of Variation," by H. N. Russell.

"Oscillations in the Periods of Cluster Variables and the Coincidence of Visual and Photographic Maxima," by Harlow Shapley.

"The Discovery of Three Naked-eye Variable Stars," by Harlow Shapley.

"Note on the Use of Diffraction Effects in Stellar Parallax Work," by Frederick Slocum.

"Observations of Nebulae with an Objective-prism Camera," by E. B. Frost and H. L. Alden.

"The Location of the Sun's Reversing Layer," by S. A. Mitchell.

"Spectroscopic Notes from the Detroit Observatory," by R. H. Curtiss.

"Spectrographic Observations of the Nebulae," by V. M. Slipher.

"The Transmission of Terrestrial Radiation by the Earth's Atmosphere in Summer and Winter," by F. W. Very.

"Note on the Spectrum and Radial Velocity of γ Persei," by Paul Merrill.

"The General Magnetic Field of the Sun," by G. E. Hale, F. Ellerman, and A. van Maanen.

"Color Equations of Photographs taken with the 16-inch Metcalf Telescope," by Henrietta S. Leavitt.

"Report of the Committee on Photographic Astrometry: I. Experiments with Wide-angle Cameras; II. Experiments with a Stationary Telescope," by Frank Schlesinger, Chairman.

The next meeting of the society will be held at Northwestern University in August of 1914.

PHILIP FOX,
Secretary

SOCIETIES AND ACADEMIES

THE ACADEMY OF SCIENCE OF ST. LOUIS

At the meeting of the Academy on January 5, Dr. Victor E. Emmel, of the Washington University Medical School, read a paper on "The Problem of the Origin of the Non-nucleated Red Blood Corpuscles."

Dr. Emmel stated that the various views which have arisen in the history of the problem may be briefly stated as including that of intra-cellular nuclear disintegration, nuclear persistence, the hematoblast theory, intra-cellular formation, and the nuclear extrusion theory. With the exception of the hematoblast theory, all of these views are still being seriously discussed, although at the present time that of nuclear extrusion has the greater number of adherents. In contrast to these theories the following results of a study of blood cultures and fresh and fixed blood of the pig embryo appear to support another possible mode of origin for the non-nucleated red blood corpuscles.

It was found that the erythroblast of the pig embryo in place of being spherical, as generally described, may in the later stages of cytomorphosis, assume a biconcave or cup shape; its nucleus becomes smaller, more compact, eccentric in position, and not infrequently flattened in form; mechanically rotated, the erythroblasts tend to orient themselves with the nuclear region remaining on the under side, as if loaded; and that their reaction to changes in osmotic conditions indicates a structural difference between the nuclear and cytoplasmic poles. These observations were discussed with reference to the question of the correlation of the form of the definite plastid with the enucleation of the erythroblast, and formation of a leucithin containing membrane, hemoglobin, differentiation, and the factors involved in determining the eccentric position of the nucleus.

In some eighty culture experiments non-nucleated erythrocytes or plastids were observed to arise from the parent erythroblast by a process of cytoplasmic constriction. In size, form, hemoglobin content and stain these culture plastids are comparable to the normal circulatory plastids. Observations on living and fixed material indicate the occurrence of a similar process within the embryo. These results accordingly raise the question whether the origin of non-nucleated red blood corpuscles by a process of cytoplasmic constriction rather than by nuclear extrusion or intracellular nuclear disintegration does not merit more serious consideration.

Now in its Third Year of publication

Editors:

F. L. Ransome C. S. Scofield F. E. Wright

Appears semi-monthly with about 600 pages a year. Aims to give a prompt and complete record of the scientific work in Washington, in the form of original papers, authors' abstracts, and the Proceedings of the fifteen Washington scientific societies. Subscription, \$6.00 a year, postpaid. Sample copies sent on request. Address, Treasurer, Washington Academy of Sciences, Washington, U. S. A.

European Agents:

William Wesley & Son, 28 Essex St., Strand, London, and Mayer & Müller, Prince Louis Ferdinand Str., Berlin.

Shells! Shells!

An unusual opportunity for some institution or conchologist. About 5,700 species and varieties; over 50,000 specimens. All correctly named and labeled. The result of 60 years' collecting. Very moderate price. Address

J. C. ROWELL

3415 West Street Oakland, California

SAVE MONEY ON CHAPCO SCIENTIFIC APPARATUS

By selling direct from our factory to schools all over the country we are able to give better quality for a given price. Chapco Purchase Guide No. 11 with its prices, illustrations and descriptions of hundreds of laboratory articles will prove this.

We will send a copy free for the asking to any instructor or school official who states his school connection. Chapco Apparatus is sold by mail direct to schools. (6)

Chicago Apparatus Co., 55 S. Clinton St. Chicago

MARINE BIOLOGICAL LABORATORY WOODS HOLE, MASS.

1. Zoology. Preserved material of all types of animals for class work and for the museum.
2. Embryology. Stages of some invertebrates, fishes (including Acanthias, Amia and Lepidosteus), Amphibia, and some mammals.
3. Botany. Preserved material of Algae, Fungi, Liverworts, and Mosses. Price lists furnished on application to GEORGE M. GRAY, Curator, Woods Hole, Mass.

PROVIDENT TEACHERS' AGENCY

120 Tremont Street BOSTON, MASS.
We enroll and we recommend teachers and officers for public and private schools, for normal and technical schools, and for colleges and universities. Vacancies now for immediate service and for 1914-15. Director, JAMES LEE LOVE, formerly of Harvard Faculty.

ROMEIKE'S

PRESS CLIPPINGS

are now an absolute necessity for every scientific man. By methodical searching through the most important papers and periodicals published in this country and abroad we are able to supply you at short notice with information on any subject which perhaps you would be unable to find yourself in libraries or reference books after spending days or even weeks at such a task. Write for further information.

CUSSENS APPARATUS

The "Atwood's Machine"

The Patented Ribbon Atwood's Machine shown in the illustration is a new form, and furnishes an excellent means of illustrating the laws of falling bodies. A graphic record of the fall is made on the paper strip, connecting the weights. The motion of a single lever allows the weight to drop, and sets the pendulum in vibration. With the use of this machine, results are obtained which cannot be approached in accuracy by any other apparatus.

Other Cussons products which have met with wide-spread approval are the Mathematical Models, Capstan Block Apparatus, Machine and Steam Engine Models, and Apparatus for Experimental Mechanics, catalogs of which, with attractive "Duty Free" price, will be sent on request.

A New Invention

The Leitz "Binocular Microscope with one objective"

This instrument causes quite a revolution in the Microscope technique.

The Binocular Microscope can be used with low and high powers, including Oil-Immersion.

The body contains a system of prisms whereby the binocular vision with the aid of two oculars is effected. A milled head allows the oculars to be placed at the proper distance to suit the interpupillary of the observer's eyes. One ocular is supplied with an adjustment for the accommodation of the difference of refraction between the eyes of the observer.

FEATURES

Restfulness to both eyes.

Image of increased brilliancy is resolved into the minutest details.

Apparent stereoscopic effect especially noticeable.

The regular objectives, available in the laboratories, can be utilized.

Price complete, without optical equipment, duty free \$79.30

Mallory's Pathologic Histology

Dr. Mallory presents *pathology* biologically. First he ascertains the cellular elements out of which the various lesions are built up; then he traces the development of the lesions from the simplest to the most complex. He so presents pathology that you are able to trace backward from any given end-result, such as sclerosis of an organ (cirrhosis of the liver, for example), through all the various acute lesions that may terminate in that particular end-result to the *primal cause* of the lesion. With a knowledge of the complete development of the lesion before you, you are better able to summarize or even to state definitely *how* the lesion arose. The book is based on the study of *the lesions themselves*—not on the literature, although the opinions of other investigators have not been ignored. The *illustrations* are most beautiful. There are 683 of them. The 124 colored illustrations are printed directly in the text. There are no troublesome inserts.

Octavo of 677 pages, with 497 figures, containing 683 original illustrations, 124 in colors. By FRANK B. MALLORY, M.D., Associate Professor of Pathology at Harvard Medical School, Boston.

Cloth, \$5.50 net; Half Morocco, \$7.00 net

McFarland's Pathology

SECOND EDITION

Dr. McFarland gives you in these 900 pages a complete survey of pathology, both *general and special*. There are chapters on the etiology of disease, defects of development, nutrition, circulation, characteristics of cell life, regeneration, retrogressive and progressive tissue changes, parasitism, immunity, infection and infectious diseases, the blood, cardiovascular, digestive, and respiratory systems, skin, spleen, lymphatic nodes, thymus gland, bone-marrow, motor apparatus, nervous, reproductive, and urinary systems.

Octavo of 856 pages, with 437 illustrations, some in colors. By JOSEPH MCFARLAND, M.D., Professor of Pathology and Bacteriology, Medico-Chirurgical College of Philadelphia.

Cloth, \$5.00 net; Half Morocco, \$6.50 net.

McConnell's Pathology

SECOND EDITION

Dr. McConnell gives you here in concise form the essentials of pathology, avoiding all unnecessary theory and discussion, adhering closely to the strictly practical. The entire field is covered, including postmortem examination, laboratory technique—fixing, decalcification, injection, imbedding, exact formulas for staining, etc.

12mo of 523 pages, 175 illustrations. By GUTHRIE MCCONNELL, M.D., Professor of Bacteriology and Pathology at Temple University, Philadelphia.

Flexible leather, \$2.50 net.

W. B. SAUNDERS COMPANY Philadelphia and London

New McGraw-Hill Books

JOHANNSEN—

(MARCH, 1914)

Manual of Petrographic Methods

By ALBERT JOHANNSEN, Ph.D., Assistant Professor of Petrology, The University of Chicago. 649 pages, 6x9, 765 illustrations. \$6.00 (25s) net, postpaid.

There is no work in English which gives complete information on modern petrographic-microscopic methods. Dr. Johannsen has filled this gap with a work of broad scope, requiring years of research and labor.

It is designed as a reference work for specialists and a text book for advanced students.

Send for full descriptive circular.

LINDGREN—

Mineral Deposits

By WALDEMAR LINDGREN, Professor of Economic Geology, in charge of the Department of Geology, Massachusetts Institute of Technology, Geologist, United States Geological Survey. 883 pages, 6x9, 257 illustrations, \$5.00 (21s) net, postpaid.

We call this book "epoch making" advisedly, because geologists generally agree that it marks a new era in the current of opinion on ore deposits.

From all over the world there have come most unusual words of praise for this book—the ripe fruit of long study, experience and thought.

STANSFIELD

(NEW SECOND EDITION)

The Electric Furnace

By ALFRED A. STANSFIELD, D.Sc., Birks Professor of Metallurgy in McGill University, Montreal. 415 pages, 6x9, 155 illustrations, \$4.00 (17s) net, postpaid.

Prof. Stansfield brings down to date the important facts relating to the theory and practise of the electric furnace.

The first edition of his book has been a standard. Since its publication in 1907, the development of the electric furnace and the increase in its use have been rapid.

The present edition is twice the size of the first—a growth made necessary both by the advance in the industry and the demand for more detailed treatment of the subject.

DALY—

(FEB. 1914)

Igneous Rocks and Their Origin

By REGINALD ALDWORTH DALY, Sturgis-Hooper Professor of Geology, Chairman of the Department of Geology, Harvard University. 563 pages, 6x9, 205 illustrations, \$4.00 (17s) net, postpaid.

For twenty years Dr. Daly has studied the earth problem as a whole, the views of other geologists, and formulated, developed and strengthened his own theory.

He has embodied the results of his study in a work for those who want either a general explanation or the significant facts.

MAHIN

(JAN. 1914)

Quantitative Analysis

By EDWARD G. MAHIN, Associate Professor of Chemistry in Purdue University. 510 pages, 119 illustrations, \$3.00.

A book that is broader in scope than the usual text. It aims to produce in the mind of the student a clear comprehension of the scientific development of quantitative methods. It is especially valuable to the commercial chemist since it devotes nearly 250 pages to the latest methods of "Analysis of Industrial Products and Raw Materials."

THE SOLAR CONSTANT OF RADIATION¹

WE live in a world warmed by the sun. While it is not to be expected that everybody will devote himself to the measurement of solar radiation, yet it is not surprising that many have concerned themselves with measuring the quantity on which all lives depend. So far as I am aware, this subject was not pursued by the ancients to such a point as to obtain measurements worth much present consideration. This is a great pity, for thus we lack proof whether the sun's radiation has changed progressively. Beginning about a century ago investigations of solar radiation were pursued with great assiduity by various observers. The need was almost immediately perceived of reducing the observations to represent conditions outside the earth's atmosphere, as, for example, on the moon, so as to be independent of the haze and water vapor and even of the gaseous constituents of the air. It is required to know the measure of solar radiation in free space as an index of the condition of the sun, quite apart from its influence on terrestrial affairs, but secondly it is of great importance and interest to apply this knowledge to promote meteorological inquiries.

Sir John Herschel, who was a pioneer in solar radiation work, proposed to express solar radiation in terms of a unit which he called the actine, which is based on the melting of ice. But by general consent the gram calorie has been adopted as the unit of measurement, and we say that the

¹ Address delivered before the Philosophical Society of Washington, January 3, 1914, as retiring president.

"solar constant of radiation" is the number of calories per square centimeter per minute which would be produced by the complete absorption of the solar radiation in free space at the earth's mean solar distance.

Preparatory researches of great interest were made in the eighteenth century by Bouguer, Lambert, DeSaussure and Leslie. Determinations of the solar constant of radiation, however, may be said to have begun about eighty years ago with the investigations of Sir John Herschel, Principal Forbes and Pouillet. The problem comprises two parts: first, to measure the intensity of the solar radiation at the earth's surface; second, to estimate the loss it has suffered in passing through the atmosphere. It will be convenient to consider the atmospheric influence briefly before taking up the methods of measuring the solar radiation, and then to return to a more thorough discussion of the atmospheric transmission.

ATMOSPHERIC TRANSMISSION

The determination of the transmission of the atmosphere rests primarily upon the hypothesis of Bouguer, first put forward in the year 1729 and elaborated in Bouguer's posthumous work published in the year 1760. The late Dr. Langley has placed this matter in so very clear a light in his paper on the "Amount of the Atmospheric Absorption"² that I can not do better than to quote from his statement.

If a beam of sunlight enters through a crevice in a dark room the light is partly interrupted by the particles of dust or mist in the air, the apartment is visibly illuminated by the light laterally reflected or diffused from them, and the direct beam, having lost something by this process, is not so bright after it has crossed the room, as before. In common language, the direct light, to an ob-

server in the path of the beam, has been partly "absorbed," and the problem is, to determine in what degree. If a certain portion of the light (suppose one fifth) were thus scattered, the beam after it crossed the room would be but four-fifths as bright as when it entered it; and, if we were to trace the now diminished beam through a second apartment altogether like the other, it seems at first reasonable to suppose that the same proportion (*i. e.*, four fifths of the remainder) would be transmitted there also, and that the light would be the same kind of light as before, and only diminished in amount (in the proportion $4/5 \times 4/5$). The assumption originally made by Bouguer and followed by Herschel and Pouillet, was that it was in this manner that our solar heat was absorbed by our atmosphere, and that by assuming such a simple progression the original heat could be calculated.

If A_0 be the intensity of the original beam before entering the transparent medium whose transmission is to be investigated, then after the passage through the first stratum of unit thickness let us suppose a fraction of the original represented by p has passed through, so that what was A_0 becomes $A_0 p$. Then since a second stratum identical with the first in constitution and thickness must, according to Bouguer's assumption, have an identical effect, the ray which was A_0 will emerge from the second stratum $A_0 p^2$, and so on. The fraction p transmitted by the unit of thickness is the common ratio of a geometric progression, so that after passing through a thickness m of the medium, the intensity of the light which was formerly A_0 will become $A_0 p^m$.

As the height to which the atmosphere extends in appreciable density is very small compared with the radius of the earth, the thickness of the layer traversed by a solar beam of a zenith distance not exceeding 70° is approximately proportional to the secant of the zenith distance of the sun at the time of observation. If we regard unit thickness as that corresponding to barometric pressure of 760

² *American Journal of Science*, Third Series, Vol. 28, September, 1884.

millimeters of mercury, then p in our formula corresponds to the vertical transmission coefficient of the atmosphere above sea level, and for any station where the barometric pressure is B the intensity of the ray from the sun as it reaches the earth's surface, which we call A , may be expressed by the formula

$$A = A_0 p^{(B/760) \sec z}.$$

Some writers have preferred to use the formula as a formula of "absorption" rather than of transmission. In that way the expression reduces to a somewhat different form, but its fundamental principles are the same. The investigations of Herschel, Forbes, Pouillet and others up to the time of Langley had reference to this exponential formula based upon the hypothesis of Bouguer, which was to the effect that successive equal layers of transparent material transmit equal fractions of the incident ray.

A convenient method of applying the atmospheric transmission formula is to take logarithms of both members of the equation so as to reduce the expression to the form of the equation of a straight line. Thus

$$\log A = \frac{B}{760} \sec z \log p + \log A_0.$$

By this equation the intercept of the best straight line on the axis of ordinates is the logarithm of the intensity of solar radiation outside the atmosphere, and the inclination of the line to the horizontal is the logarithm of the atmospheric transmission for vertical rays.

The reader must bear in mind that the simple expression thus far obtained is given only in illustration of the work of the earlier investigators, and it must be hedged about with certain conditions and limitations in order to apply it, as we shall see later, to the determination of the solar

constant of radiation by the most approved methods.

INSTRUMENTS

Herschel's Actinometer.—This instrument consists of a thermometer with a large cylindrical bulb, containing a deep blue fluid (the ammoniacal sulphate of copper) and enclosed in a wooden case blackened interiorly and covered with a piece of thick plate glass. The thermometer has a very large bulb, and it is adjusted in volume by means of a screw, so as to regulate the position of the column of liquid on the thermometer scale. Herschel introduced what is termed the dynamical method of observing the solar radiation, for he obtained not the total rise of temperature of the instrument when long exposed to the sun, but its initial rate of rise, corrected for the cooling or warming of the thermometer due to external conditions when the sun is shaded. The determination of the cooling correction is done by observing the rise or fall of the temperature for a certain time interval before exposing to the sun, and again determining the rise or fall after such exposure to the sun is completed. The mean rate of warming or cooling, due to the surroundings, is applied as a correction to the rate of warming due to the exposure to the solar radiation.

Pouillet's Pyrheliometer.—A flat metal box, blackened on the front, and filled with water, had a thermometer inserted at the rear, extending away from the direction of the sun. The instrument, like that of Herschel, was exposed to the influence of the surroundings while shaded for a certain interval of time the shade was then removed for a similar interval so as to allow the solar radiation to fall upon the blackened box, after which the instrument was again shaded. In practise it was found that the water within the box could not be well enough stirred in order to allow the average

temperature of the water to be well ascertained. The instrument was greatly improved by Tyndall, who substituted mercury for water, and, in order to contain the mercury, used iron in the making of the box.

Crova Alcohol Actinometer.—A large spherical bulb thermometer containing alcohol is enclosed in a nickel-plated metal chamber with a vestibule for the entrance of the rays. The stem of the thermometer runs back, directly away from the sun, and is enclosed in a nickel-plated tube with a side opening for reading the thermometer. A short mercury thread is introduced in the alcohol column at a suitable point for observing. The method of observing is the same as that adopted by Herschel and by Pouillet.

Violle Actinometer.—A large spherical double-walled enclosure filled with water is kept at a known constant temperature. A spherical blackened-bulb thermometer lies at the center of the enclosure, and the sunlight is introduced to it through a suitable vestibule in the double-walled chamber. Violle's method of reading was static, as opposed to the dynamic methods we have just considered. He observed the total rise of the thermometer and its fall after the cutting off of the sun rays, noting the position of the column at fixed intervals after exposure and after closure. The theory of the instrument as developed by Violle is simple and elegant. As a standard the instrument is open to the objection that the water equivalent of the bulb of the thermometer is very small, and difficult to measure, and that several corrections rather difficult of determination should be applied. It was used by Dr. Langley in his expedition to Mount Whitney in 1881.

Ångström Electrical Compensation Pyrheliometer.—This instrument has had the most extensive adoption in recent years of

any form of instrument for measuring the solar radiation. It was invented about the year 1895. Two metal strips exactly similar to one another, and blackened upon the front, are exposed alternately to heating by the sun. Arrangement is provided for passing an electrical current through the strip which is not at the moment being heated by the sun. Thermo-elements fastened to the back of each strip indicate when the temperature of the exposed strip is equal to that of the strip which is electrically heated. Under these circumstances it is assumed that the energy of the electric current is equal to the energy received from the sun. About 160 copies of this electrical compensation pyrheliometer have been sent out from Upsala to different parts of the world.

Several other kinds of pyrheliometers have been used in recent years, among them two forms which have been devised by the writer. We shall have occasion to speak of these later.

EARLY OBSERVATIONS

Forbes observed with the Herschel actinometer in the year 1832 at Brientz and the Faulhorn. He showed that the transmissibility of sun rays continually increases as the length of path of the ray in air increases. Forbes rightly attributed this to the non-homogeneity of the solar radiation, and the inequality of transmission of the different component parts of it. Under such circumstances Bouguer's formula of course can not apply. Forbes concluded that equal barometric columns of air give equal transmission, whether taken from the high or low station. In this he was wrong. He formed an empirical curve to represent all his observations at both stations, employing air masses as abscissæ and actinometer readings as ordinates. Instead of extrapolating this curve directly to air

mass zero he preferred to find its tangents and thus derive the subsidiary curve of tangents from which he derived a formula for extrapolating his observations. In this way he obtained results corresponding to the value 2.85 calories per square centimeter per minute for the solar constant. Thus Forbes cut loose entirely from Bouguer's exponential formula of atmospheric transmission.

Pouillet observed in the years 1837 and 1838 at Paris. His work was published before that of Forbes, although made later. He found transmission coefficients by means of Bouguer's formula. He apparently did not investigate the defects of this formula as thoroughly as Forbes did. His result for the solar constant of radiation is 1.7633 calories per square centimeter per minute. This value, on account of the non-homogeneity of the solar rays, is necessarily too low.

Quetelet observed with a Robinson actinometer similar in form to Herschel's, at Brussels from the year 1843 to 1853. These experiments might well repay a critical examination now, not for their value in determining the absolute measure of the solar constant of radiation, but in connection with the variation of the average intensity of the solar radiation from year to year as influenced by volcanic eruptions.

Desains employed a thermopile, and compared the transmissibility of the rays of the sun through a water cell at different stations. He found the transmissibility of solar rays through the water cell always increased by a long preliminary course through moist air. This result is essentially the same as that of Forbes, although obtained in a different manner.

Violle observed at many different stations, including Mont Blanc. His instrument apparently read much too high, as

noticed by Langley in the report of the Mount Whitney expedition. He used a somewhat complicated empirical formula of extrapolation, as he was fully cognizant of the defect of Bouguer's formula, as indicated by Forbes. He obtained the following values:

	Outside Atmosphere	Mt. Blanc	Grand-Mulet	Bossons	Paris.
Altitude.....	—	4,810	3,050	1,200	60
Barometer.....	0	430	533	661	758
Calories.....	2.54	239	2.26	2.02	1.74

These values should be reduced about one fourth to make them comparable with observations made in recent years at high elevations by many observers. In such a case the value outside the atmosphere would become about 1.9 calories per sq. cm. per minute.

Crova made many observations at Mont-Pellier with his alcohol actinometer standardized against the Tyndall pyrheliometer. He made some attempts to extrapolate his observations to the limit of the atmosphere, but these, like other solar constant values obtained by pyrheliometry alone, are not definitive. Great value, however, attaches to the long series of direct observations continued from the year 1883 to 1900 at Mont-Pellier. These show plainly the influence of the volcano Krakatau and others.

K. Ångström observed with the electrical compensation pyrheliometer at several stations at different altitudes on the island of Teneriffe in the years 1895 and 1896. Some of his measurements were made at the altitude of 3,700 meters, and give direct readings of solar radiation as high as 1.63 calories per square centimeter per minute. Ångström declined to determine from these a value of the solar constant of radiation, recognizing that this demanded observations of the solar spectrum as well as pyrheliometric work. In later years he

prepared spectro-bolometric apparatus for this purpose, and made many solar constant measurements therewith at Upsala. These measurements are still being continued there by his successors. It is hoped that this long and interesting series will soon be published.

Passing from this work of Ångström, which belongs in a later period, and omitting mention of valuable pyrheliometric observations by numerous observers in Italy, Switzerland and Russia, which I regret that space forbids me here to discuss, attention must now be directed to the work of Langley, which marked an epoch in this kind of investigation.

LANGLEY'S OBSERVATIONS

Prior to Langley's observations there had been numerous attempts to determine the solar constant, which are well summed up in the excellent little book of Radau, entitled "Actinometrie." It is shown that nearly all observers were in comparative agreement, so far as their actual observations go, and if the transmission of radiation by the atmosphere be estimated by the simple formula

$$A = A_0 p^{B/760 \text{ sec } z},$$

which was employed by Pouillet and many others, the value of the solar constant would be found in the neighborhood of 1.75 calories.

But Forbes, Desains, Violle, Crova and others showed convincingly that this equation does not accurately express the diminution of radiation attending the decline of the sun from zenith to horizon, or the descent of the observer from a high altitude to a lower one. Accordingly several empirical formulæ of more complexity were proposed, which, owing to their more numerous constants, could be made to fit the observed variation of the total intensity of radiation under different conditions more

closely. By the aid of such empirical formulæ higher values of the solar constant have been obtained. Some of these in our own time have gone as high as 4 calories. Radau however says:

It is clear that the intensity of the solar radiation outside the atmosphere can not be certainly obtained from experiments which have been made [prior to 1871], for the result depends essentially on the manner of calculation.

This conclusion is still applicable to pyrheliometer measurements not supported by spectrum observations.

The tendency toward high values of the solar constant was powerfully stimulated by the publication of the report of the Mount Whitney expedition by Langley in 1884. As Forbes and Radau had stated, so Langley emphasized and acted upon the fact that the formula

$$A = A_0 p^{B/760 \text{ sec } z},$$

applies only to a homogeneous bundle of rays in a pure atmosphere; and the intensity of solar radiation outside the atmosphere can only be exactly determined when the atmospheric transmission coefficients of the rays of all wave-lengths, which go to make up the complex beam of the sun, are separately determined and allowed for. Langley was the first to determine and apply atmospheric transmission coefficients for numerous rays of different wave-lengths in the solar spectrum. For this purpose he invented the bolometer, a delicate electrical thermometer, and observed with it the variation of the intensity of each ray of the spectrum from low sun to high. He found it impracticable to determine the transmission coefficients in the water vapor bands of the infra-red, but assuming that there were no water vapor bands in the solar spectrum outside our atmosphere, he avoided this difficulty by smoothing the spectrum energy curve, which he computed from his bolometric observations to repre-

sent the distribution of solar radiation outside the atmosphere, so as to leave no water vapor bands in it at all. Had Langley stopped with these steps accomplished, he would have left us, as the result of the Mount Whitney expedition, 2.060 calories, the mean value as determined by high and low sun observations at Lone Pine, or 2.220 calories, the mean value similarly determined from observations at Mountain Camp. But, by the train of reasoning given on pages 142-144 of his report, he convinced himself that the exponential formula does not hold for the earth's atmosphere, even for a strictly homogeneous ray. He therefore altered his results by two different procedures, one of which he states was of a kind to give too low a value of the solar constant, and the other too high. By this means he obtained the values 2.630 and 3.505. The mean of these, 3.068, or in round numbers 3.0 calories per sq. cm. per min., he adopted as the solar constant. But in fact, both procedures were calculated to give too high results, and the most probable results of Langley's observations lies below either of them, and is in fact 2.22, or 2.06 calories, according as the work at Lone Pine or Mountain Camp is regarded as the better. In order to recognize this, it is necessary to examine the argument which led him to doubt the accuracy of the exponential formula, as applied to the transmission of homogeneous rays through the earth's atmosphere, but first let us consider the basis of the formula.

We have seen that Bouguer's formula rests on the fundamental assumption that the light is not changed in its nature in passing from one layer to another, so that equal layers take out equal fractions. This is not the case except for homogeneous rays. It is therefore necessary to divide the beam up into parts, each containing rays of ap-

proximately homogeneous transmissibility. For this purpose it is necessary to observe the spectrum of the sunlight by the aid of the bolometer or other satisfactory delicate heat-measuring instrument. Even so, it is not possible to observe the transmission of the atmosphere at every wave-length, so as to determine the coefficients of transmission in the fine lines of absorption by water vapor and oxygen which are introduced by the earth's atmosphere. These lines are mainly grouped in the great bands made up of these fine lines which occur in the red and infra-red spectrum, and for them a special procedure must be adopted as was introduced by Langley. In general, however, the bolometer suffices to give us atmospheric transmission coefficients in sufficient number to deal with the gradually changing transparency of the air for rays of nearly adjacent wave-lengths. The proof of the formula for atmospheric transmission for homogeneous rays follows: It will be seen that the formula is one of extrapolation solely, and is not applicable to computations of the transparency at different barometric pressures, unless it be the fact (which is not usual) that the quality of the air from the different stations to the limit of the atmosphere is approximately identical. This indeed may be the case at very high elevations of 4,000 meters and over, but is not the case for ordinary observing stations, so that in the use of the formula of transmission it is generally erroneous to introduce the barometric pressure in the exponent as was done by Pouillet.

PROOF OF FORMULA FOR TRANSMISSION

Imagine the atmosphere to be made up of n concentric layers so chosen in thickness as to produce separately equal barometric pressures, and let the number n be so great that the transparency of any single layer is sensibly uniform, although the layers may differ from each other in trans-

parency by any gradual progression. The index of refraction of air is so near unity that there will be no sensible regular reflection in passing from one layer to the next, and the transmission of each layer may be expressed exponentially by Bouguer's formula, but with different coefficients of transmission for the several layers.

Thus, suppose E_0 to be the original intensity of a beam of light incident upon the outermost layer at the angle whose secant is m .

Then after passing successive layers the remaining intensities become

$$E_1 = E_0 a_1 m_1, \quad E_2 = E_0 a_1 m_1 \cdot a_2 m_2, \\ E_n = E_0 a_1 m_1 a_2 m_2 \dots a_n m_n. \quad (1)$$

The value of the secant of the angle of incidence will change slightly in passing from layer to layer from two causes: first, the curvature of the earth; second, the refraction of the beam in air. These causes produce opposite effects, the first tending to increase the angle of incidence, the second tending to diminish it as the beam approaches the earth's surface. Their combined effect is dependent on the height to which the temperature exercises absorption and on the distribution of density with the height. But it is generally supposed that the absorption of the air above 40 miles from the earth's surface is negligible, and, remembering that the atmospheric density diminishes with the height, it appears that for zenith distances less than 70° the effect of change of the secant of the angle of the incident beam from the outermost to the innermost layer of the atmosphere will not introduce error greater than 1 per cent. Accordingly for zenith distances less than 70° we may write approximately

$$E_n = E_0 (a_1 a_2 \dots a_n) m. \quad (2)$$

The symbols $a_1, a_2 \dots a_n$ denote constants (providing no change of transparency occurs during the interval of time in question), and their values are slightly less than unity. We may substitute for their product a single constant, a , itself a proper fraction, and remembering that E_n is the intensity at the earth's surface, above denoted simply by E , we have

$$E = E_0 a^m. \quad (3)$$

LIMITATIONS OF FORMULA

No mention is made in this expression of the barometric pressure, but it is easy to see that an alteration of barometric pressure would signify, under the conventions adopted in deriving the

formula, a change in the number of layers, n . This would cause an alteration of the quantity a , which is the continued product of the transmission coefficients of the layers, by introducing additional multipliers $a_{n+1}, a_{n+2} \dots$ or by the withdrawal of some $a_{n-1}, a_{n-2} \dots$. Since we have no means of determining the value of the terms so introduced or taken away, there is no means of correcting for change of barometer in the use of the expression (3) and it would, for instance, be impossible to compute, from knowledge of the values of E, E_0, a and m for one station; what would be the value of E at some station of different barometric pressure.

From this we see that the unit of air mass to be taken for each station is the air mass traversed by beams from zenith celestial objects *between the station itself and the outer limit of the atmosphere*, and that the barometric pressure can not be employed in the computation to reduce observations at different stations to a common unit of air mass.

The determination of the solar constant of radiation, based upon the demonstration which has just been given, depends upon the following assumptions:

1. In a homogeneous medium, a homogeneous ray loses a fixed proportion of its intensity in every equal length of its path.
2. The earth's atmosphere may be considered as made up of a great number of layers concentric with the earth, each approximately homogeneous in itself over the area swept through by the solar beam between zenith distances of 70° and 30° during the time required for this sweep of the beam.
3. Surface reflection of the outer boundary of the atmosphere, or the boundaries of its internal layers, is negligible.
4. Except in the known red and infrared atmospheric bands, the transparency varies gradually from wave-length to wave-length, or if atmospheric absorption lines exist, the energy they absorb is inconsiderable.

5. Atmospheric bands do not exist in the solar spectrum outside the atmosphere.

6. The quantity of solar energy beyond $\lambda = 0.3 \mu$ in the ultra-violet and beyond $\lambda = 3.0 \mu$ in the infra-red is inconsiderable.

The soundness of these assumptions is best proved by the results of a great number of observations made at sea level and at high altitudes during the last ten years by different observers, but mainly by the staff of the Astrophysical Observatory of the Smithsonian Institution.

DISCUSSION OF LANGLEY'S SOLAR CONSTANT VALUE

With this preliminary we may perceive why the high solar constant value of Langley ought not to be accepted. For this purpose consider lines 26 to 43 of page 144 of the Mount Whitney report, which detail the precise method employed in obtaining what Langley regarded as a minimum value, namely 2.63 calories per square centimeter per minute.

We now proceed to determine from our bolometer observations a value which we may believe from considerations analogous to those just presented, to be a *minimum* of the solar constant, and one within the probable truth. All the evidence we possess shows, as we have already stated, that the atmosphere grows more transmissible as we ascend, or that for equal weights of air the transmissibility increases (and probably continuously), as we go up higher. In finding our minimum value we proceed as follows, still dealing with rays which are as approximately homogeneous as we can experimentally obtain them. Let us take one of these rays as an example, and let it be one whose wave-length is 0.6μ and which caused a deflection at Lone Pine of 201. The coefficient of transmission for this ray as determined by high and low sun at Lone Pine and referred to the vertical air mass between Lone Pine and Mountain Camp is 0.976. From the observations at Lone Pine then, the heat of this ray upon the mountain should have been

$$201 \times 1,000 \div 976 = 206.0,$$

but the heat in this ray actually observed on the

mountain was 249.7, therefore multiplying the value for the energy of this ray outside the atmosphere, calculated from Mountain Camp high and low sun observations (275) by the ratio $249.7/2060$ we have 333.3, where 333.3 represents the energy in this ray outside the atmosphere as determined by this second process. In like manner we proceed to deal with the rays already used, thus forming column 8 in Table 120.

It is evident that the transmission coefficient determined for the wave-length 0.6μ by the aid of high and low sun observations at Lone Pine, represented the mean transmission of a ray of this wave-length through a mass of air containing all the kinds of strata between Lone Pine and the limit of the atmosphere. Such a transmission coefficient would certainly be greater than that which would have been found if the air had all been like that between Lone Pine and Mountain Camp, because the lower layers are least transparent,³ therefore the value 0.976 could be known, *a priori*, not to represent the transmission of the air between Lone Pine and Mountain Camp, but to be certainly greater than the true transmission coefficient for the air between these stations. Accordingly the discrepancy between the computed and observed intensities at Mountain Camp is only what should be expected, and implies no failure of the formula of Bouguer at all; for that formula was used in the computation of the intensity at Mountain Camp just quoted with a coefficient p which was certainly wrong. The argument on which Langley acted may be stated in a plausible form as follows: If Bouguer's exponential formula with the transmission coefficient obtained by high and low sun observations at Lone Pine gives too low a value of the intensity of homogeneous solar radiation for a station within the atmosphere like Mountain Camp, as was shown by actual observation, much more will it

³ See Table 118 of the Mount Whitney Report.

give too low a value outside the atmosphere. An equally plausible, and equally fallacious argument is the following: It is said that the density of water decreases with increasing temperature at the mean rate of about .00041 per degree from 0° to 100°. Hence its density at 4° should be 0.99836, but observations at 4° prove that water is actually denser at this temperature than at 0°, therefore the supposed decreased density at 100° is a delusion.

SOLAR CONSTANT WORK OF THE SMITHSONIAN
ASTROPHYSICAL OBSERVATORY

The earlier years of the work of the Astrophysical Observatory were devoted to the improvement of the bolometer and the use of it for the determination of the positions of lines in the infra-red solar spectrum. About 1902 attention began to be devoted to measurements of the solar constant of radiation. We approached these measurements with a very much better instrumental equipment than that which had been Langley's in the Mount Whitney expedition of 1881. Soon after the Astrophysical Observatory was founded, about the year 1890, Langley introduced the automatic registration of the galvanometer in connection with the spectro-bolometer, and in the subsequent years the difficulties connected with the use of the recording spectro-bolometer were so far overcome that the solar spectrum could be observed from the extreme ultra-violet end of the spectrum at about 0.3μ to a wave-length of about 3μ in the infra-red with great ease and accuracy, in an interval of 8 minutes of time. Drift of the galvanometer, which in Langley's expedition to Mount Whitney he has told me often amounted to a meter a minute on the scale, was now so far reduced that a centimeter an hour would be unusual. In fact the bolometer, despite its great sensitiveness, is about as easy to use for this

work as an ordinary thermometer is for measuring the temperature of the air.

Our first measurements of the sun's radiation as a whole were made with the Crova alcohol actinometer, and in order to standardize this instrument we constructed a modified Tyndall pyrheliometer consisting of a copper box filled with mercury and having a cylindric bulb thermometer inserted radially into the box. Owing to the difficulty of keeping the small thread of mercury at the proper point for reading purposes in the Crova actinometer, we found it more desirable to develop the pyrheliometer for our purpose. Soon a solid disk of copper with a radial hole large enough to enclose the thermometer bulb was substituted for the box filled with mercury, the use of mercury being limited to insuring a good heat connection between the bulb of the thermometer and the copper of the disk. Some of these copper disk pyrheliometers are still in use on Mount Wilson. About 1909, however, the further improvement was introduced of using silver in place of copper for the disk. A thin steel lining is provided for the hole where the thermometer is inserted, so as to prevent the mercury from alloying with the silver. In these silver disk instruments the thermometer stem, which is introduced radially in the disk, is bent outside the chamber at right angles so as to point towards the sun. The whole instrument is mounted equatorially with a device for moving it by hand to follow the sun from moment to moment. These disk pyrheliometers, either of copper or silver, have now been in use since the year 1906 with great satisfaction. Their constancy over long periods of time leaves nothing to be desired, and the accuracy of observation reaches a small fraction of 1 per cent.

As the disk pyrheliometer is a secondary instrument, it was necessary to develop a

standard primary instrument to compare it with. As early as the year 1904 experiments were begun to produce a pyrheliometer based upon the hollow chamber "black body" type, with a flowing liquid to carry off the heat produced by the absorption of the solar rays within such a chamber. After numerous experiments and long trial the waterflow standard pyrheliometer was fully developed in the year 1910. Later still, another hollow chamber instrument in which the chamber is bathed with stirred water was employed to check the results of the standard water-flow instruments. In each of these types of standard instruments it is possible to introduce electrically known quantities of heat for testing purposes, and in many experiments it has been proved that the test quantities of heat thus introduced may be recovered to within 1 per cent. Accordingly it is believed that the standard scale of radiation has been thoroughly established. The silver disk instruments are standardized by comparing them with such standard instruments, and the standard scale of radiation so produced, which is believed to be accurate to at least $\frac{1}{2}$ of 1 per cent., has been diffused generally over the world by the Smithsonian Institution. About 25 copies of the silver-disk pyrheliometer have been standardized and sent out to Europe, North America and South America for this purpose. The Smithsonian instruments read about 3.5 per cent. above those of Ångström.

Measurements of the solar constant of radiation were begun in Washington in the year 1902 and have been continued at Washington and elsewhere in every succeeding year until the present time. In 1903 it was noticed that the values of the solar radiation outside the atmosphere obtained in Washington were distinctly variable within the limits of about 10 per cent., and as some of the changes appeared to

occur between days which were of the highest order of excellence, it was thought possible that these changes might occur in the sun, and not be caused by alterations of the transparency of the earth's atmosphere. To test this possibility, a station was established on Mount Wilson, California, in the year 1905 by invitation of Director Hale of the Mount Wilson Solar Observatory. The station proved to be very favorable for the work, and in 1908 a permanent structure of cement was built there for the use of the Smithsonian Astrophysical Observatory. In the years 1909 and 1910 spectro-bolometric observations for the determination of the solar constant of radiation were also made on the extreme summit of Mount Whitney in California at an altitude of 4,420 meters. At the same time observations were being made at Mount Wilson at an altitude of 1,730 meters. The results from these two stations reduced to outside the atmosphere at mean solar distance, like those which had formerly been obtained simultaneously at Washington and Mount Wilson, were identical within the limit of the accuracy of the determinations. The accuracy of the work at Mount Wilson and Mount Whitney was so great that the average divergence between the observations of the same days was only 1 per cent. At Washington the sky conditions being less perfect, the average divergence from simultaneous solar-constant results of Mount Wilson was about 3 per cent.

EVIDENCES OF SOLAR VARIABILITY OF SHORT IRREGULAR PERIODS

Numerous observations of several years at Mount Wilson indicated a fluctuation in the solar constant values having a range of about 10 per cent. The fluctuations seemed to occur irregularly, sometimes running their course of 10 per cent. or less

within the period of a week or ten days, and at other times keeping nearly constant. It had been shown by the observations made simultaneously at Mount Wilson and at Mount Whitney that the results as reduced outside the atmosphere appear to be independent of the altitude of the observing station on days when the sky conditions appeared to the eye to be excellent. The march of the apparent fluctuation of the solar constant values at Mount Wilson has not been of a hap-hazard character. I mean by this that the values would progress in a definite direction, as for instance from a low value to a high value by steps through several successive days, and then as definitely progress in the opposite direction through other successive days, and do not fluctuate widely from high values to low as would be the case if the irregularities were due merely to instrumental error. Since, then, it appeared that the fluctuations were neither of an accidental instrumental character nor of a character associated with the altitude of the observing station, it appeared most reasonable to conclude that these fluctuations were due to changes in the sun's emission.

To test this important conclusion it appeared necessary to establish a second station, equally favorably situated with regard to sky conditions as Mount Wilson, but so far remote from Mount Wilson that local influences could not be expected to alter the results at both stations in the same direction on the same day. Such a station was established at Bassour, Algeria, in the years 1911 and 1912. Seventy-five days of simultaneous measurement at Mount Wilson and at Bassour were obtained, and of these days about 50 were so far free from the occurrence of clouds or other disturbing influences at *both* stations as to be retained for purposes of comparison. The result of the comparison shows that when

high values are obtained at Bassour, high values are obtained also at Mount Wilson and *vice versa*. Thus the fluctuations which have been found appear to be truly existing in the solar radiation outside the earth's atmosphere, for the solar constant values obtained at two stations separated by about one third the circumference of the earth unite in showing them.

VALUE OF THE SOLAR CONSTANT

During the whole solar constant campaign from 1902 to 1913, about 700 measurements of the solar constant of radiation have been obtained, all but three of the values ranging between 1.80 calories and 2.10 calories. The range of these numbers is mainly attributable to the actual fluctuation of the sun itself, though part, especially in Washington work, is due to accidental errors of measurement. The mean value from 690 measurements is 1.933 calories per square centimeter per minute. It is believed that this number represents the average value of the solar constant of radiation for the epoch 1902 to 1913 within 1 per cent. There is still the possibility, however, that an appreciable quantity of solar radiation beyond the wave-length of 0.3μ in the ultra-violet has been absorbed by ozone in the higher atmosphere of the earth, and has been impossible of determination at the stations employed. However, from the consideration of the form of energy curve of the sun's spectrum it is improbable that this lost ultra-violet radiation can exceed 1 or 2 per cent.

SOLAR VARIABILITY ASSOCIATED WITH SUN-SPOTS

Besides the short irregular fluctuation of solar radiation above mentioned as having been shown by the simultaneous measurements at Mount Wilson and Bassour,

Algeria, it appears that a long period fluctuation is associated with the sun-spot numbers. This connection is brought out by taking the mean monthly values of the solar constant measurements at Mount Wilson from the year 1906 on, and comparing them with the mean monthly sun-spot numbers of Wolfer for the same period. From such a comparison it appears that the greater number of sun-spots the higher will be the solar constant of radiation, and that an increase of a hundred sun-spot numbers corresponds to an increase of about 0.07 calories per square centimeter per minute in the solar radiation outside the earth's atmosphere. This is a very curious circumstance, when it is recalled that the temperature of the earth is generally lower at sun-spot maximum than at sun-spot minimum, notwithstanding that, if the above result be true, the solar radiation is more intense at sun-spot maximum than at sun-spot minimum. On the other hand, the result is in line with the irregular variability of the Myra type of variable stars.

ATMOSPHERIC TRANSMISSION

In connection with the measurements which have been made of the solar constant of radiation, there have been some interesting by-products. Among these we may mention first the determination of the transmission coefficients of the earth's atmosphere for light of all wave-lengths, including the ultra-violet and the infra-red spectrum, and ranging from wave-length 0.3μ in the ultra-violet to wave-length 2.5μ in the infra-red. These transmission coefficients have been obtained by the Smithsonian observers at Washington, Mount Wilson, Mount Whitney and Bassour. It is very interesting to compare them with the transmission of the atmosphere as computed according to the theoretical consideration of Rayleigh on the

cause of the light of the sky. It is found that by means of these observed transmission coefficients the value of the number of molecules in the atmosphere may be obtained almost as accurately as by the use of the more common laboratory methods for determining the number of molecules per cubic centimeter of a gas of known density. It is found that the theory of Rayleigh connecting the change of transmission with the wave-length is closely confirmed by the observations at Bassour, Mount Wilson and Mount Whitney. Similar measurements of atmospheric transmission for more limited regions of the spectrum have been made by other observers at high altitudes, and these also are found to agree closely with the theory of Rayleigh, and with our own observations.

Not less interesting is the determination of the distribution of energy in the sun's spectrum, and thereby of the probable temperature existing in the sun. The solar temperatures may be inferred also from the value of the solar constant of radiation itself, and the two methods agree substantially in giving the probable solar temperatures as between 6,000 and 7,000 degrees absolute centigrade.

RECENT BALLOON EXPERIMENTS

Notwithstanding the satisfactory state of the theory of solar constant measurements by the method of Langley, depending upon spectro-bolometric observations at high and low sun combined with measurements by the pyrheliometer, and notwithstanding the close agreement between results obtained by this method for many years at stations of differing altitude from sea-level to 4,420 meters elevation, there still exists the possibility that if we could, indeed, go outside the atmosphere altogether we should obtain values differing materially from those above given. So

long as we observe at the earth's surface, no matter how high the mountain top on which we stand, the atmosphere remains above us, and some estimate must be made of its transmission before the solar constant can be determined. Different persons will differ in the degree of confidence which they will ascribe to measurements of the atmospheric transmission, such as have been considered, and there are still some who totally disbelieve in the accuracy of the results thus far obtained, even though they be confirmed by observations at such differing altitudes. Accordingly it has seemed highly desirable to check the results by a method of direct observation by the pyrheliometer, attaching the instrument for this purpose to a balloon and sending it to the very highest possible altitudes. By a cooperation between the Smithsonian Institution and the United States Weather Bureau, experiments for this purpose were made in July and August of the year 1913.

The instruments employed were modified in form from the silver-disk pyrheliometer, which has been described above. As the apparatus could not be pointed at the sun the disk was placed horizontally, and the thermometer was contrived to record its temperature by photography upon a moving drum. The receiving disk was alternately exposed to the sun and shaded by the intervention of a shutter, operated intermittently by the clock work which rotated the drum under the stem of the thermometer. Five instruments of this kind were sent up on successive days. While it was well known that the temperature of the higher air would go as low as -55° C., it was believed that a blackened disk exposed half the time to the direct sun rays, would certainly remain above the temperature of -40° , which is the freezing point of mercury. This expect-

tation was disappointed. Accordingly, owing to the freezing of the mercury in the thermometer, the highest solar radiation records obtained during the expedition were at the altitude of 13,000 meters, although the balloons in some instances reached the altitude of 33,000 meters.

The results obtained, while they have not the same degree of accuracy as those obtained by direct reading of the silver disk pyrheliometer, are yet of considerable weight. All the measurements unite in indicating values of the solar radiation at altitudes of 10,000 meters and higher, which fall below the value of the solar constant of radiation as obtained by other methods, and above the value of the radiation at the summit of Mount Whitney as obtained by different observers with pyrheliometers. It is expected in the coming year to repeat the observations with balloons under much improved circumstances. By aid of electrical heating apparatus it is expected to keep the surroundings of the disks at approximately the freezing temperature, even though exposed to the air at temperatures as low as -55° C. In this way it is hoped to obtain good pyrheliometer measurements as high as it is possible for sounding balloons to go, and possibly to an altitude of 40,000 meters. As the atmospheric pressure at such altitudes is less than 1 per cent. of that prevailing at sea level, the experiments, if successful, may be expected to remove reasonable doubt of the value of the solar constant of radiation.

C. G. ABBOT

SETH CARLO CHANDLER

DR. SETH CARLO CHANDLER, eminent astronomer, died on December 31, 1913, in his sixty-seventh year after a short attack of pneumonia.

Born at Boston, Mass., September 17, 1846,

the son of Seth Carlo and Mary (Cheever) Chandler, he spent his early childhood in and around Boston. He attended the English high school at Boston, graduating in 1861, but did not pursue a collegiate course as he had already become interested in mathematical computations while still at the high school, being employed upon the computations of Professor Benjamin Peirce. After graduation he joined Dr. B. A. Gould as private assistant and thus obtained his first taste for astronomical subjects. Dr. Gould was at that time busily engaged in developing the longitude-determinations of the Coast Survey, and through him Dr. Chandler joined the U. S. Coast Survey as aid in 1864. Later when Dr. Gould made his historic expeditionary trip to the Argentine Republic, which eventually resulted in the establishment of a national observatory by the Argentine government, Dr. Chandler refused an offer to accompany the expedition in favor of a position as actuary with the Continental Life Insurance Co. of New York, removing to New York City. It was shortly after this that he married Miss Caroline M. Herman, of Boston, on October 20, 1870.

Seven years later he returned to Boston to accept a position as consulting actuary for the Union Mutual Life Insurance Co. of Boston.

But though his life had been thrown into other channels, Dr. Chandler still felt an interest in astronomical subjects, so it was not surprising that with Harvard College Observatory so near at hand, he should have joined the work of the observatory. Astronomers had long felt the need of some system of communicating such discoveries as comets in order that such objects might not be lost through the inability to observe them at any one station. Realizing this need, Dr. Chandler and Mr. John Ritchie formulated a code for the speedy transmission of discoveries by telegraph to observatories all over the United States. Though the system has been revised, it is still being operated by the Harvard College Observatory.

It was during his connection with Harvard

College Observatory that Dr. Chandler invented and constructed the almuercator, an instrument for measuring stellar positions.

After the year 1886 he became a private investigator. There are many instances of men who, while deriving their source of income from other professions, have become interested in astronomy, and who have accomplished remarkable results; but among these there is none to compare with Dr. Chandler, whose whole soul seemed wrapped up in his astronomical investigations.

When one considers that he was the author of over two hundred articles, it can readily be imagined what a serious interest he took in his chosen field, and what a hard worker he was. It has been remarked of many authors that they have only written when the spark of genius inspired them. So it was with Dr. Chandler, who at times would take an almost complete rest from his astronomical labors, only to enter one orgie after another of concentrated effort. While under the spell of one of these sieges, nothing could divert him, but once over it he was ready for any form of diversion or entertainment, taking a great interest in many outside affairs.

As an astronomer Dr. Chandler will possibly be chiefly remembered for his work upon variable stars, and for his historic discovery of the variation of latitude. As a result of his discovery of the variation of latitude, international latitude stations have been established at different points of the earth in order to study the periodic shifting of the earth's pole. Dr. Chandler treated a great variety of other subjects with thoroughness.

For his brilliant work he received the Watson medal of the National Academy of Sciences in 1895, and in 1896 he received the gold medal of the Royal Astronomical Society. De Pauw granted him the degree of LL.D. in 1891.

Upon the death of Dr. Gould, founder and first editor of the *Astronomical Journal*, Dr. Chandler assumed the editorship, which he held during the period 1896-1909, resigning at the latter date because ill health prevented

him from performing his editorial duties. Until his health broke down he had devoted not only much time to the *Astronomical Journal*, but considerable aid from his private purse, a truly conclusive proof of his great interest in the *Journal*.

Personally Dr. Chandler was a man of large interests and a ready sympathy. Those who knew him will remember with pleasure his entertaining and brilliant conversation and correspondence. He was possessed of a broad sense of humor and a keen wit, at once a source of delight to his friends and a weapon to be shunned by his enemies.

BENJAMIN BOSS

DUDLEY OBSERVATORY

*THE AMERICAN ASSOCIATION FOR THE
ADVANCEMENT OF SCIENCE¹*

*REPORT OF THE ASSOCIATE SECRETARY
FOR THE SOUTH*

THE associate secretary entered upon his duties October 1, 1913. The first work was to prepare a circular letter which was forwarded to each of the 538 members of the association then residing in the territory of the thirteen southern states assigned by the permanent secretary. The text of this letter follows:

Dear Sir: The next annual meeting of the American Association is to be held at Atlanta, Ga., from December 29, 1913, to January 3, 1914.

To insure its success every member must cooperate.

We desire a large attendance and full programs. This is your opportunity to show your loyalty to the Association and your interest in its aims. Make it a point to be present and to participate in the discussions.

The Association has not the membership in our section which it should have. There has never been a time when the active cooperation of scientists was of such importance as it is to-day. The need of such cooperation is especially marked in the South. We need to get together, to exchange views and to stimulate scientific work. We need to exert our collective influence to secure better support for scientific activities, and

¹ Presented to the Council at the Atlanta meeting.

greater discrimination in the filling of scientific posts.

The Atlanta meeting of the American Association offers an opportunity for southern men of science to show the country at large that a progressive spirit animates our section and that the cause of higher education and scientific research is being fostered among us.

Will you not constitute yourself a committee of one to secure new members and promote the Association's interests this year?

Enclosed are several membership application cards. Others will be supplied on request. Please make an effort to secure new members from among your colleagues, and urge their attendance at the meeting.

A stamped envelope is enclosed for your reply. I shall be glad to address personal letters to any individual whom you may suggest as eligible to membership. Please also make suggestions as to methods of procedure in advancing the work of the Association in your section.

Let each one do his part and the advancement of science in the South will be materially furthered by the Atlanta meeting.

Cordially yours,

Associate Secretary

With this letter there were enclosed two membership application cards and a stamped return envelope.

In addition a list of 37 members was selected from the representative colleges and universities of the southern states. To each of these a special letter was sent, the text of which follows:

Dear Professor: I am endeavoring to assist Dr. Howard in connection with the Atlanta meeting of the American Association, and I wish to request your personal cooperation.

It is unnecessary to urge upon you the importance of the American Association for men of science, and the obligation which rests upon us in the South to make the coming meeting a success. But if we would demonstrate to the other sections of the country that the South takes an active interest in the advancement of science, we must energetically encourage our colleagues to attend the Atlanta meeting.

I am addressing a circular letter to each southern member of the Association, a copy of which I enclose. But I wish to ask of you special assistance in your own institution.

I find that the following members of your faculty are enrolled in the Association: ———. Will you not mention to each of these the importance of the Atlanta meeting and urge his attendance and participation?

There are doubtless many others in your community who are eligible to membership. We should like to receive all whom you can recommend, and to welcome them at Atlanta. I enclose several membership application cards and will send others on request.

If you will suggest their names, I shall be glad to write them individually, or, if you think it advisable, I can visit your institution at some time in the fall which we can agree upon, for the purpose of interviewing these men personally, and possibly to speak before the men of science in your community.

Will you not write to me in regard to the matter, and let me know just what you think may be the best method for interesting the present members, and increasing the roll from your institution?

Very cordially yours,
Associate Secretary

From these 538 communications 120 replies were received. Of the special letters 24 were acknowledged. Of the total number of replies 44 recommended persons for membership.

The following table indicates the distribution of members and the acknowledgments received.

State	Total Number	Total Acknowledgments	Number Submitting Names for Membership
Alabama.....	31	9	5
Arkansas.....	11	3	2
Florida.....	27	2	0
Georgia.....	59	15	7
Kentucky.....	29	3	1
Louisiana.....	47	7	3
Mississippi.....	18	9	4
North Carolina.....	38	12	3
South Carolina.....	27	8	3
Tennessee.....	51	19	6
Texas.....	83	14	3
Virginia.....	86	10	5
West Virginia.....	28	6	2
Removed from territory	3	3	0
	538	120	44

Letters of invitation were sent to each person thus suggested for membership in the

association. This number was greatly augmented by the names of eligible persons otherwise secured. The total number of such invitation letters was 255. A membership application card and return envelope were enclosed with each letter, also one of the association leaflets of information.

Acceptances were received from 37 to whom these invitations were extended. In addition, 22, who may or may not have been influenced by these communications to members, applied directly to the permanent secretary. The total enlistment for the territory was therefore 59.

These were distributed by states as follows:

Ala.	6	N. C.	4
Ark.	0	S. C.	7
Fla.	2	Tenn.	14
Ga.	4	Texas	8
Ky.	1	Va.	5
La.	5	W. Va.	3
Miss.	0	Total	59

The associate secretary made two trips in the interests of the association. On October 31 the meeting of the Southern Educational Association at Nashville was attended. On invitation of the president, Hon. M. L. Brittain, the secretary addressed a general meeting of the association, urging the cooperation of southern educators in the work of the American Association for the Advancement of Science, and extending a cordial invitation to be present and participate in the Atlanta meeting.

In response to the requests received from institutions, a ten-day trip was undertaken, commencing November 30, during which the following colleges and universities were visited:

University of Mississippi,
Miss. A. and M. College,
Ala. Polytechnic Institute,
Georgia School of Technology,
University of Georgia,
Davidson College, N. C.,
Clemson College, S. C.

At all these, excepting Davidson College, an address was made before the faculties of the institutions. The topic chosen for discussion was that of cooperation among scientists.

The remarks were informal, dealing with various aspects of scholarly work, and the great need of a more active interest in the advancement of science in southern institutions. These gatherings were all well attended and the discussion led in several places to an active participation on the part of various members of the faculties concerned.

In view of the efforts made by the association to stimulate a greater interest in scientific advancement in the south, the results of this campaign have not been as encouraging as they should be. In the opinion of your secretary there are various reasons for this condition of affairs, but too much space would be required to consider them here at any length. A few points may, however, be mentioned to indicate the general state of science in southern colleges and universities:

1. Outside the agricultural experiment stations, scientific research is not usually encouraged. There is a widespread notion that research and teaching are inimical. Since few southern institutions can afford the luxury of men engaged primarily for research, it is commonly agreed to dispense with this feature of higher education and concentrate upon the employment of "good teachers."

2. The teaching hours of the faculties are often considerable. Almost never are they short of 15 periods per week, and sometimes they run as high as 40. The large number of different courses which one man is thus required to undertake, to say nothing of his participation in committee work of various sorts, leaves him with neither energy nor time for research.

3. The salaries paid to professors are usually inadequate. The men are thus unable to get away to graduate institutions on sabbatical leave or during the summer for special work in their respective fields.

4. There is little active competition in the filling of vacancies, since the openings are infrequently made public before the positions are filled. Furthermore, the compensation of full professors is commonly uniform, hence there is no stimulus within the institution for

advancement of salary in recognition of activity along research lines.

5. The instructors and younger men of the faculties are often recruited from recent graduates who have had little experience in advanced work and often have not definitely determined upon a university career. They therefore lack the stimulus of advancement in their profession through original work, and fail to appreciate the value of national gatherings of scientific men, as providing inspiration, and affording an opportunity for personal contact with men in their own lines of endeavor.

Respectfully submitted,

R. M. OGDEN

December 30, 1913

*MINUTES OF THE SECOND MEETING OF
THE PACIFIC COAST COMMITTEE*

THE committee met on February 7, 1914, in Parlor B of the Palace Hotel, San Francisco.

Present: Chairman Campbell, President Branner, Mrs. Moody, Dr. MacDougal, Professors Haskell, Jenkins, Kellogg, Kofoid, Kroeber, Lawson, Leuschner, E. P. Lewis, Martin, Merriam, Sanford, Setchell, Stillman; Professor Louderback representing the Pacific Association of Scientific Societies, and Commissioner Barr representing the Panama-Pacific Exposition.

It was voted that ten should constitute a quorum.

The minutes of the last meeting, as printed in *SCIENCE*, were approved.

It was voted to strike out the word "Coast" in the designation "Pacific Division."

The report of the executive committee, presenting resolutions of policy, was discussed, and with some amendments, finally adopted as follows:

1. It shall be the purpose of the Pacific Division of the American Association for the Advancement of Science to promote the interests of science through formal and definite cooperation with all Pacific Coast scientific societies of good standards already in existence, and to organize sections in necessary lines of work for which no other provision has been made, such sections to be maintained only until the subjects shall be otherwise

provided for by the organization of affiliated societies.

2. The times and places of meeting of the division shall be decided by a committee consisting of a representative of the division and one representative of each of the affiliated societies.

3. The division shall organize or maintain no sections for the presentation of technical programs in the lines represented by affiliated societies. The technical programs shall be organized by the separate societies, with one member of the division council as a member of the program committee of each society.

4. Individual members of societies need not become division members, and division members need not join societies, but the privileges of those members belonging only to the division to present worthy papers in the proper programs and to take part in the discussions should be recognized.

5. All general sessions, public lectures, appointments of committees for general scientific purposes, etc., shall be controlled by officers of the Pacific division.

6. The constituents of the Pacific division shall be the individual members of the American Association for the Advancement of Science living in the territory defined by the original resolution establishing the Pacific division, and such constituent societies existing within this territory as are up to standard and which shall apply for membership and be accepted by the division, all societies at present constituents of the Pacific Association of Scientific Societies to have the privilege of affiliation until July 1, 1916.

The appointment of a subcommittee to draft a constitution for the Pacific Division was referred to the executive committee with power to act.

A special committee consisting of Director Campbell, Dr. MacDougal and Professor Merriam was appointed to select the associate secretary with power to act. (This committee met later in the day and appointed Albert L. Barrows to this position.)

Professor Lawson presented the report of the committee on the time and place of meeting. The report of the committee was finally adopted with some amendments as follows:

1. The American Association for the Advancement of Science should maintain a central office in San Francisco during the time of meeting.

2. The general sessions of the meeting should be held in San Francisco.

3. The evening lectures should be given in San Francisco.

4. The sectional meetings should be held chiefly in Berkeley.

5. There should be one day's session for sectional meetings at Stanford University.

6. The time of meeting should be the first week in August, 1915.

The chairman stated that Director Hale had declined the chairmanship of the committee on scientific program on account of his health, and that a new appointment would be announced later. (President J. C. Branner has since consented to become chairman of this committee.)

Adjourned to meet at the call of the chair.

E. P. LEWIS,

Secretary.

SCIENTIFIC NOTES AND NEWS

PROFESSOR J. H. COMSTOCK, of Cornell University, has received one of the twelve honorary memberships of the Société Entomologique of Belgium.

THE Franklin Institute of the State of Pennsylvania has awarded its Elliott Cresson gold medal to Professor Wolfgang Gaede for his molecular air pump, in consideration of the very great value of this invention for the quick production of vacua beyond those hitherto obtainable.

THE Cameron prize of the University of Edinburgh has been awarded to Professor Paul Ehrlich in recognition of his discovery of salvarsan and other contributions to medical science.

PROFESSOR ERNST NEUMANN, the pathologist of Königsberg, has been given an honorary doctorate of medicine at the University of Geneva on the occasion of his eightieth birthday.

M. HENRI BERGSON, professor of philosophy at the Collège de France, has been elected to membership in the French Academy.

PROFESSOR J. G. FRAZER has been elected a member of the Athenæum Club for "distinguished eminence."

ARRANGEMENTS are being made for a reception and dinner in honor of Professor Ira O. Baker, '74, of the University of Illinois, at the Hotel LaSalle in Chicago, on March 17. About four hundred are expected to be present and the list of speakers will include some of the most prominent engineers of the west. Professor Baker completes in June, 1914, forty years of active, continuous service as a member of the faculty of the college of engineering of the University of Illinois.

DR. WOLFGANG OSTWALD, professor of chemistry in the University of Leipzig, Germany, was given a banquet on February 11, by the Cincinnati Chemical Society and the Cincinnati Society for Medical Research.

PROFESSOR J. PAUL GOODE, of the University of Chicago, has completed the second pair of wall maps in the series upon which he has been engaged for some years. This pair consists of the physical and political North America. The first pair on the physical and political Europe were issued some months ago. There are to be eighteen maps in the series, all of which are nearing completion.

LEWIS E. MOORE, associate professor of structural engineering at the Massachusetts Institute of Technology, has resigned to become bridge engineer for the Massachusetts Public Service Commission.

PROFESSOR HERGESELL, head of the Meteorological Institute of Strassburg, has been appointed director of the Aeronautical Laboratory at Lindenberg, in succession to Professor Assmann.

PROFESSOR A. A. IWANOW has been appointed director of the University Observatory at St. Petersburg.

DR. MARTIN STRELL has been appointed assistant in the Biological Experiment Station for Fisheries at Munich.

PROFESSOR E. C. BRYANT, of Middlebury College, Professor L. L. Campbell, of Simmons College, and Professor W. E. McElfresh, of Williams College, are spending their sabbatical year at the Cavendish Laboratory of Cambridge University, and are carrying on researches under Sir J. J. Thomson.

PROFESSOR HENRY TSCHETSCHOTT, of the St. Petersburg Mining Institute, has registered at the Massachusetts Institute of Technology for special work. His coming to the institute is part of a general plan of the government to educate Russians abroad for positions as teachers in the home schools. Already there are at Technology two other Russians, Messrs. Penn and Ortin, who have likewise been sent by the government.

DEAN CHARLES R. BARDEEN, of the school of medicine of the University of Wisconsin, delivered the annual address of the University of Iowa chapter of Sigma Xi, February 18, on "The Effect of Physical and Chemical Agents on Development."

UNDER the auspices of the Rush Society, the College of Physicians of Philadelphia, the University of Pennsylvania, the Philadelphia Pathological Society, and the Mutter Museum, the Weir Mitchell lecture for 1914 was given on February 25, by Dr. Harvey Cushing, professor of surgery at the Harvard Medical School, on "Clinical types of dyspituitarism."

THE Harvey Society lecture on February 28, at the New York Academy of Medicine, was given by Professor Richard P. Strong, of Harvard University, on the etiology of oryza fever and verruga peruviana.

"THE Nebular Hypothesis" was the subject of an illustrated lecture given on March 2 by Professor Forest Ray Moulton, of the department of astronomy and astrophysics in the University of Chicago, at the Berwyn center of the University Lecture Association, Chicago. On March 16 Professor Moulton speaks at the same place on the subject of "The Sidereal Universe."

DR. WOLFGANG OSTWALD delivered his series of five lectures on colloids at the Ohio State University during the week ending February 21. A more popular lecture designed to interest beginners in chemistry was delivered for the benefit of the freshmen class.

THE foreign mathematicians who attended the Fifth International Congress of Mathematicians held at Cambridge in 1912 subscribed a sum to be devoted to a permanent

memorial to the late Sadlerian Professor, Dr. Cayley. We learn from the London *Times* that, having in mind that the presidency of this congress was the last public appearance of Sir George Darwin, his colleagues in the administration of the congress have desired to provide a memorial of his work in the same connection. Accordingly a brass plate with armorial decorations has been prepared, and is now offered by Sir Joseph Larmor on behalf of his colleagues to the university. It is proposed to fix this brass in the chief mathematical lecture-room in the new lecture-rooms building.

MR. H. B. WOODWARD, F.R.S., formerly assistant-director of the British Geological Survey, died on February 6, aged sixty-five years.

MAJOR G. E. H. BARRETT-HAMILTON died on January 17 in South Georgia, where he was conducting an investigation into the whaling industry on behalf of the Colonial Office and the British Natural History Museum.

DR. KARL BÖLCKERS, professor of ophthalmology at Kiel, has died at the age of seventy-eight years.

WE regret also to record the death of M. Alphonse Bertillon, the distinguished French anthropometrist.

THE Russian minister of public instruction has made a grant of \$50,000 to the St. Petersburg Academy of Sciences to assist a search for radio-active minerals throughout the Russian Empire.

CANADA has established a forest products laboratory in connection with McGill University at Montreal, on the lines of the United States institution of the same sort at the University of Wisconsin.

PROVISION is to be made in connection with the French department of war for continuing the aerological work carried on by the late M. Léon Teisserenc de Bort, at his observatory at Trappes.

THE annual general meeting of the American Philological Society will be held on April 23, 24 and 25, 1914, beginning at 2 P. M. on Wednesday, April 23. Members are requested to send to the secretaries, at as early

a date as practicable and before March 5, 1914, the titles of papers which they intend to present so that they may be announced on the preliminary program which will be issued immediately after that date and which will give in detail the arrangements for the meeting. Papers in any department of science come within the scope of the society which, as its name indicates, embraces the whole field of useful knowledge. The publication committee, under the rules of the society, will arrange for the immediate publication of the papers presented in either the *Proceedings* or the *Transactions*, as may be designated.

THE fifth International Congress of Philosophy will be held in London beginning on August 31, 1915, under the presidency of Dr. Bernard Bosanquet. The sections proposed are: (1) General Philosophy and Metaphysics. (2) Logic and Theory of Knowledge. (3) History of Philosophy. (4) Psychology. (5) Æsthetics. (6) Moral Philosophy. (7) Social Philosophy and Philosophy of Law. (8) Philosophy of Religion. All communications should be directed to the honorary secretary of the congress, Dr. H. Wildon Carr, More's Garden, Chelsea, London, S.W.

THE territory within a mile or two of each of the mouths of the Mississippi is characterized by large swellings or upheavals of tough bluish-gray clay, to which has been applied the name "mud lumps." Many of these mud lumps rise just offshore and form islands having a surface extent of an acre or more and a height of 5 or 10 feet, but some do not reach the water surface. These mud lumps, in addition to being of importance because of their effects on the channels of the Mississippi River, are also of considerable scientific interest, for their development is not included in the usual conception of delta growth, and although several theories have been advanced, their cause must still be regarded as uncertain. To an observer at the mouth of the river the idea that the region is a great dumping ground for a large part of the United States is most impressive. The land is being built out into the sea at an estimated average rate of about 300 feet a year; in some places the rate is much more rapid than in others. In

one place in Garden Island Bay the land appears to have advanced 2,000 feet in the spring of 1912. The mud lumps are commonly 20 to 30 rods broad and stand 20 or 30 feet above the adjacent bottom. Their growth occupies from a few hours to several years and is usually irregular. Generally a mud lump rises in a few weeks or months to a height of 4 or 5 feet above the surface of the water. Then it remains quiet and is beaten down by the waves in the course of a few years. Many of them subside, however, and some disappear over night. Those that rise slowly are considerably worn before they stop growing, while those that rise more rapidly and in protected places are capped by laminated silt having a maximum thickness of 10 feet. Among the most conspicuous and impressive features of the mud lumps are the mud springs that are active on many if not all of them. The discharge from these springs consists of salt, watery mud and gas—in fact, gas escapes at many places on the surface of the Delta of the Mississippi, the vents appearing to be most numerous and largest on and near the mud lumps, though the rate of flow rarely, if ever, exceeds a few cubic feet an hour. Gas rises in bubbles in all the mud springs, though its rate of issue varies. The United States Geological Survey has issued a report entitled "The Mud Lumps at the Mouths of the Mississippi," by Eugene Wesley Shaw—a copy of which may be obtained free on application to the director of the survey, Washington, D. C.

UNIVERSITY AND EDUCATIONAL NEWS

THE observance of Washington's birthday at Lehigh University was marked by the dedication of Coppee Hall, the new home of the arts and science department. The building is named after Dr. Henry Coppee, who was the first president of Lehigh University.

TEACHERS COLLEGE, Columbia University, celebrated its twenty-fifth anniversary on February 20 and 21, with an educational conference which brought together nearly one thousand alumni and former students of the institution. During Friday and Saturday a series of educational conferences was held at

the college devoted to different divisions of the educational fields as follows: Administration and College Teachers of Education, Secondary Education, English, History, Geography, German, Mathematics, Science, Elementary Education, Kindergarten Education, Fine and Industrial Arts, Household Arts, Nursing and Health, Household Administration. The speakers included superintendents of schools, deans of university schools of education, directors of normal schools and specialists from various educational fields, college, secondary and elementary. Saturday night nearly 800 alumni gathered for a dinner at the Aldine Club. The program of the science round table was as follows:

"Use of Literature in Science Teaching," by Clarke E. Davis.

"Trend of the Times," by J. Newton Gray.

"A Method for Teaching Nutrition in the High School."

"Chemistry for Second-year High School Girls," by Henry T. Weed.

"General Science—A Method and Its Difficulties," by Roland Hugh Williams.

"An Experiment in Teaching Heat," by Carl J. Hunkins.

PROFESSOR A. L. DEAN, of the Sheffield Scientific School, Yale, has accepted the call to the presidency of the college of Hawaii, at Honolulu, and will take up his duties there next autumn.

At the Massachusetts Institute of Technology Mr. J. M. Barker has been appointed instructor in civil engineering and Miss Edith A. Beckler, lecturer on public health laboratory methods.

DR. H. F. BAKER, F.R.S., fellow of St. John's College and Cayley lecturer in mathematics, has been elected Lowndean professor of astronomy and geometry in the University of Cambridge in succession to the late Sir Robert Ball.

THE Manchester University Council has appointed Dr. Charles Alfred Edwards to the chair of metallurgy and metallography.

DR. E. E. FOURNIER D'ALBE, assistant lecturer in physics in the University of Birmingham, has been appointed special lecturer in physics in the University of Punjab, Lahore.

DR. LUDWIG DIELS, of Marburg, has been appointed associate professor of botany in the University of Berlin, and assistant director of the Botanical Garden and Museum.

DISCUSSION AND CORRESPONDENCE

FOSSIL PLANTS IN THE PANAMA CANAL ZONE

EXCEPT for the incidental mention by Pilsbry and Brown of lignified nuts in their paper on the Mollusca I know of no record of any remains of fossil plants having been found in the Canal Zone, notwithstanding the fact that the numerous Tertiary tuffs would seem to furnish an admirable matrix for the preservation of leaf impressions.

During 1912 Dr. M. I. Goldman, of the Johns Hopkins University, visited the Isthmus and in connection with his work on rock weathering devoted considerable time to a search for fossil plants along the Canal with the results indicated by the following note.

Since fossil plants of Tertiary age from the tropics have not been collected or studied to any large extent and since the Tertiary floras of Central America have a most important bearing on both the phytologic and geologic history of southeastern North America during the Tertiary, a preliminary announcement seems justifiable.

Fossil plants seem to be somewhat sparsely but widely distributed along the canal and identifiable forms were collected from the following localities:

1. East wall of the Culebra Cut just north of station 1760 and opposite Culebra.
2. West wall of cut below Miraflores locks, where the plant-bearing tuff outcrops for about one fourth of a mile.
3. Culebra Cut under the steep hill just north of Paraiso, associated with specimens of the pelecypodian genus *Phacoides*.
4. Gatun Dam borrow pits.

The best material comes from the first of these localities and the least satisfactory from the last. The collections have not been critically studied, since it is hoped that more extensive collections will be sent in by the resident geologist of the Canal Commission.

The following forms have been recognized

in a preliminary study of the collection: A fine large species of *Guatteria* which is present at several localities; a well-marked species of *Myrtaceæ*, probably representing the genus *Calyptanthus*; a species of *Nectandra*; a species of *Rhamnaceæ*; a characteristic small-leaved species of *Ficus*; another of *Ocotea*; a species of *Rubiaceæ* and one of *Melastomaceæ*. Petrified wood was also collected and although but three slides have been cut these show apparent identity with a species described from the Oligocene of the Island of Antigua.

None of the material lends any support to the view, at one time prevalent, that some of the Isthmian beds represent deposits of Eocene age, and while the various plant-bearing beds are probably not exactly synchronous, their floras in so far as they are known from the present small collection all appear to be referable to the Oligocene.

JOHNS HOPKINS UNIVERSITY,
BALTIMORE, MD.

WHAT GRADES REPRESENT

THE following considerations have been of service to the writer in the diagnosis of the difficulties encountered by students in meeting the scholastic requirements represented by grades, and the identifying of the obstacles has often assisted in their removal.

It is not necessary in this discussion to assume any more definite or uniform system of grading than that 100 per cent. represents a perfect grade and that there is a minimum grade required to entitle the student to credit for the course. Half way between these is what may be called an average grade. This does not mean the grade that a class would average under the usual conditions, but what a class might be expected to average if all members gave all the officially allotted time (or a reasonable time) and their best effort to the subject—quite a different matter! The instructor should make his demands such that the student of average qualifications using his best effort all the allotted time would receive the average grade—half way between the passing grade and 100 per cent.

The main factors represented by grades intelligently given may be described by the six terms: time, effort, mental ability, memory, language sense and preparation. The relative importance of these factors varies widely with the nature of the subject, but all are involved in every intellectual pursuit. The order chosen is that of directness of control by the student.

Time.—This includes both that in attendance on classes and that given to the subject outside of class hours. Irregularity of attendance on classes and deficiency of outside preparation would have their obvious results in this factor, irrespective of the reasons for such irregularity or deficiency.

Effort.—This factor includes the practise of concentration in and out of class, largely a result of past habits; thoroughness of thought, which passes nothing until really grasped; and system, which insures sustained and continuous work as opposed to cramming at intervals.

Mental Ability.—This is evidenced by the ease and accuracy with which new ideas are grasped. It is of course largely a natural endowment, developed, however, or allowed to deteriorate, slowly by its exercise or its disuse. This factor is most important in subjects of a strongly reasoning character.

Memory.—By this term is meant the retaining of ideas rather than the memorizing of words or symbols; it is mainly a natural endowment but somewhat subject to cultivation by mental activity.

Language Sense.—By this is meant the ability to understand and to use language with precision. It is probably to some degree a natural gift, but is also largely a result of early training and associations and an appreciation of its importance. The student who can not express his own ideas clearly usually receives only vague impressions from his oral or printed instruction. The language sense can be cultivated by sustained effort directed to that end.

Preparation.—This includes general education along intellectual lines, to which appeal can be made for analogies and illustrations. It also means a proper command of the earlier part of the same subject and of other subjects

directly used as foundational material and as tools; grades wisely given in these antecedent subjects indicate clearly the adequacy of this direct preparation. It is in this factor that the student who has habitually aimed at passing rather than grasping his curriculum encounters the natural consequences in his increasing difficulties.

In conclusion it may be noted that time and effort are under immediate control; mental ability, memory and language sense are subject to slow cultivation; and preparation is beyond present control. Of course less than all the allotted time, or less than the student's best effort, or less than an average rating in factors, would necessitate correspondingly higher values for the other factors that an average grade might be earned.

LAFAYETTE, IND.

SCIENTIFIC BOOKS

Elementary Studies in Botany. By JOHN M. COULTER, A.M., Ph.D., Head of the Department of Botany, University of Chicago. New York and Chicago: D. Appleton and Company. 12mo. Pp. ix+461.

It is a pleasure to note the gradual approach to a standard course of study in botany for the high schools of the country, and there can be no question that such an approach to standardization is occurring if one will look over the text-books prepared during the last few years. Especially is this tendency marked where the authors combine a considerable experience in the teaching of botany with a comprehensive knowledge of the science. The book before us is an excellent illustration of this fact, which the author recognizes in the opening paragraph of his preface, and which is so good that we quote it complete. "It is seven years since 'A Text-book of Botany' was published, and during this period there has been not only great progress in the knowledge of plants, but also much discussion concerning the effective use of plants in high school education. It is natural that a discussion of this kind should lead to considerable

diversity of opinion, and it is evident that no one is in a position as yet to decide the points at issue. Amid all the flux of opinion, however, there is evident a desire to relate plants more closely to the interest and to the need of high school students. This desire expresses itself in an extreme form when courses in 'agriculture' are asked to be substituted for courses in 'botany.' This has brought a distinct temptation to publishers and to authors to 'meet the demand' without much consideration as to its significance. It can not mean that all that has proved good in the older method is to be abandoned, and an unorganized mass of new material substituted for it. It can not mean that high school pupils are to become apprentices rather than students. It must mean that the structure and work of plants are to be so studied that this knowledge will enable the student to work with plants intelligently. In other words, it is intended to be the practical application of knowledge, rather than practical work without knowledge."

It would be well for teachers of botany of all classes to carefully read these sentences, which gain in strength and significance to the end of the paragraph. As the writer of this review has insisted over and over again, botany wherever taught must be botany, and not some application of botany, or some study of plants not involving the orderly sequence of structural and physiological inquiry. Agriculture, horticulture, plant breeding, forestry, etc., are most excellent subjects of study for young people (and older people, for that matter), but they are not botany; rather, they require botany as a prerequisite, and must be based upon it.

Coming to Dr. Coulter's text-book we find twenty-seven chapters arranged in two "parts." Chapters I. to XIV., inclusive, deal with what may be called "pure" botany, and in these the pupil is taken step by step from the simpler to the more complex plants and their principal functions. This part of the book is intended to afford a good half-year's work for the high school pupils, and without doubt this is one of the best formulations of

this work which has yet appeared. In looking through the chapters one finds nothing which can well be omitted, nor anything which imperatively demands admission. In the second part, which is entitled "Plants in Cultivation" one finds also not a little of pure botany. Thus the chapter "What Plants Need" is plant physiology, pure and simple, as is also the chapter on "What the Soil Supplies." There is a little concession to the "practical" in the chapters on "Seeds," "Other Methods of Propagation" and "Plant Breeding," and considerably more in those on "Cereals and Forage Plants," "Vegetables," "Fruits," etc., and yet in even the most "practical" of these one sees that the presentation is by one who is primarily a botanist. All through this second part the living plant as a *plant* is emphasized, rather than the plant as a crop to be sold for such and such a sum. And here is perhaps the line of difference between the scientific conception of plant study and the conception held by those who think of plants as things to be grown for our use or pleasure. Dr. Coulter's book is a demonstration of the possibility of presenting much of applied botany in a scientific manner.

CHARLES E. BESSEY

THE UNIVERSITY OF NEBRASKA

The Evil Eye, Thanatology and Other Essays.
By ROSWELL PARK. R. G. Badger, Boston.
1913.

This volume consists of a series of entertaining essays, which, as the author states, "partake of the character of studies in that border-land of anthropology, biology, philology and history which surrounds the immediate domain of medical and general science." The subjects include *The Evil Eye*, *Thanatology* (the study of the nature and causes of death), *Serpent Myths and Serpent Worship*, *Iatro-Theurgic Symbolism*, *Giordano Bruno*, *The Career of the Army Surgeon*, *The Evolution of the Surgeon from the Barber*, *History of Anesthesia and the Introduction of Anesthetics in Surgery*, etc. The treatment in nearly every case is primarily historical, and the main purpose appears to be to show how many

customs and ideas of to-day have roots in the past which are hardly suspected by the general public. On the whole, the book makes melancholy reading, unless one can enjoy the contrast between ancient follies and our own astonishing superiority! The study of past error and confusion is certainly of value as exhibiting the weak spots in our social organism, and enabling us to be on our guard against early symptoms of decay in the societies to which we belong. Thus, the author says:

"If one attempt to scan the field of the history of medicine, to take note of all the fallacies and superstitions which have befogged men's minds, and brought about what *now* seem to be the most absurd and revolting views and practises of times gone by, and if one search deliberately for that which is of curious nature, or calculated to serve as a riddle difficult of solution, he will scarcely in the tomes which he may consult find anything stranger than the close connection, nay, even the identity maintained for centuries, between the trade of the barber and the craft of the surgeon. Even after having studied history and the various laws passed at different times, he will still miss the predominant yet concealed reason for this state of affairs. This will be found to be, in the words of Paget, the 'maintenance of vested rights as if they were better than the promotion of knowledge.'"

It is impossible to contemplate this history without asking whether to-day the "concealed reason" mentioned by Paget is not still powerful, and serving to prevent our academic institutions from readily adapting themselves to their social environment. From another point of view doubt may be expressed as to the complete validity of the author's historical method. From time to time we find fault with the professional historian, who, depending on documentary evidence, seems to over-emphasize the miseries and stupidities of former days. We like better our Morris and Scott, who offer us pictures of moving life, full of romance, adventure and high ideals. It is easy to criticize such writings, as we criticize the landscape artist who makes idyllic pictures of

suburban lanes, leaving out the tin cans, dead cats and evil smells. Yet after all, life was life in those days, and the best that is in us calls across the ages to the best that equally existed in our ancestors. Dr. Park's accounts may be true as to facts, and yet to some extent misleading to those who have not other sources of information.

T. D. A. COCKERELL

BETTER BECOMING PARASITES

IN all the great group of beetles, 50,000 species strong, and of an extraordinary variety of external appearance and of habit, witnessing to a ready plasticity and adaptiveness, there are but few indications of a resort to parasitism as a shift for a living. The Stylopidae, it is true, are parasites (in the bodies of wasps, bees and leaf hoppers), but these insects are no longer considered to be aberrant beetles, but to constitute a quite distinct order, more nearly allied to the Hymenoptera or Diptera than to the Coleoptera.

The classic and single conspicuous example of a parasitic beetle, living all of its life (both larval and adult) on its host, is the well-known beaver parasite, *Platypsylla castoris*, common both in Europe and America. This insect lives as an external parasite among the hairs on the outside of the host's body, and feeds on the hairs and dermal scales, just as the Mallophaga (biting bird lice), of birds and mammals, do. It has a highly modified body, and is the only species of its genus and family.

Another small beetle, however, *Leptinus testaceus*, of the family Leptinidae, is known in both Europe and America as a frequenter of the nests of field mice, shrews and other small mammals of similar habit. It has also been taken from bumble bees' nests. I have recently received several specimens of this beetle which were taken from the bodies of freshly killed shrews on Forrester Island, Alaska, by Professor Harold Heath. The beetle's body is not modified (by flattening, fusion of thoracic segments, etc.) in any such extreme way as is that of *Platypsylla* or the Mallophaga, but it shows, nevertheless, the

beginnings of such adaptive modification, and suggests plainly that the beetle's habits are probably already those of a habitual external parasite of its shrew and field mouse hosts, feeding (with simple biting mouthparts) on the dermal scales and hair.

Professor Van Dyke, of the University of California, our foremost Pacific coast student of the beetles, and from whom I have most of the information used in this note, writes that from the fact of finding *Leptinus* in the nests of bumble bees a number of entomologists have advanced the idea that the beetle lives normally in bumble bee nests and becomes accidentally carried from them by mammals that raid the nests. "This I do not agree with," says Dr. Van Dyke. Considering all of the circumstances of the few captures that have so far been made of the beetles, Dr. Van Dyke concludes that the beetle is a real parasite of the mice and shrews and "absolutely dependent on them in the same way that the Mallophaga are dependent on their hosts."

Another little beetle, *Leptinillus validus*, closely related to *Leptinus*, occurs on beavers in the Hudson Bay region. Still another beetle, *Lyrosoma opaca*, a Silphid (carrion beetle), is found in the North Pacific upon practically all of the islands and isolated ocean rocks to be found there. It breeds in rotten kelp and among old and broken murre's eggs, etc., and has been found prowling about the tenanted nests of the murre. But it is wingless, and Dr. Van Dyke believes that it is carried from island to island and rock to rock by the roosting and breeding birds of these rocks and islands, the beetles accidentally seeking shelter among the feathers of brooding or perching birds, and thus being carried off by them when they take to flight. "Only in this way," writes Professor Van Dyke, "can I account for the presence of the beetles on Bogoslov Island [the famous recent volcanic island of Alaska], for this island is but little over one hundred years old, and the insects are so delicate that they could not possibly survive longer than a few minutes in the Arctic waters."

These stages in the change from a scav-

enger's life to that of an external parasite, shown by the series of beetles referred to in this note, are exactly parallel with the transition stages from the wingless Atropids (Procidæ) feeding on dry bits of dead organic matter, even to the feathers and organic detritus in birds' nests, to the Mallophaga, feeding on the same bits of feathers and dermal scales, but finding them on the bodies of the birds themselves, to whom they have come to bear the relation of permanent external parasites, with no longer any capacity to live off their hosts. The next step for some of the beetles to take would be to become like the Anoplura, and find a more acceptable food in the blood of the hosts. For this their mouthparts would have to be considerably modified, but that would be no difficult matter.

SPECIAL ARTICLES

THE DECOMPOSITION OF SOIL CARBONATES

It has been found at the agricultural experiment station of the University of Tennessee, that excessive amounts of magnesium carbonate were entirely decomposed when left in contact with fallow soils in pots protected from leaching. Three types of soil were used, and the amounts of chemically pure precipitated carbonate of magnesia, equivalent to 16,000 pounds per acre of calcium carbonate were applied, in excess of the lime requirement, as indicated by the Veitch method. One year after the application the soils were analyzed and found to be strongly alkaline, but practically free of carbonates. Repetition of the experiment in metal rims, using 32,000 pounds of magnesium carbonate per acre, under field conditions, afforded the same observation in every one of eight treatments, four with magnesium carbonate alone and four with carbonate supplemented by manure, the analyses being made in this series after an eight weeks' period of contact. This work was begun in the spring of 1912 and final analyses were made in August, 1913.

It has hitherto been held that the conver-

sion of calcium and magnesium carbonates into silicates in soils has been due entirely to replacement of sodium and potassium and other bases in polysilicates. The writer and associates will shortly present in bulletin form conclusive evidence that magnesium carbonate reacts with and is fixed by silica (SiO_2), and that calcium to a less degree acts in the same manner.

Titanium oxide, which chemically is closely allied to silica and which is usually present in soils, was found to bring about the same decomposition as silica. The evidence secured points strongly to the nonexistence of magnesium in the form of carbonate in soils of humid climates.

It is believed that this research will throw considerable light upon the use of dolomite in farm practise.

THE AMERICAN ASSOCIATION FOR THE
ADVANCEMENT OF SCIENCE
SECTION C—CHEMISTRY

On the forenoon of Wednesday, December 31, joint sessions of Sections B and C were held in the Georgia School of Technology, with Vice-president Cole, of Section B, in the chair. The purpose of the meeting was a discussion of geochemical and geophysical topics; it is referred to further in the report of Section B.

The main sessions of Section C were held at the Winecoff Hotel on Thursday, January 1, with Dr. C. L. Alsberg, vice-president of the section, in the chair. This was a joint meeting with the Georgia Section of the American Chemical Society, the secretary of which had assisted in arranging the program. There was an attendance of between fifty and sixty, and considerable interest was evinced in all of the papers presented. In the evening a smoker—which indeed partook rather of the nature of a dinner—was tendered to the visiting chemists by the Georgia Section of the American Chemical Society; a number of topical verses and songs were sung and the whole affair was most enjoyable. The secretary desires to record here on behalf of the visiting chemists their appreciation of the hospitality of the Georgia

Section and to express thanks to it and to its secretary, Mr. J. S. Brogdon, for contributing so much towards the success of the meeting.

A brief account of the proceedings is appended.

The following resolution, presented by Professor Charles E. Munroe, was carried unanimously:

WHEREAS the Committee of this Section on Nomenclature and Notation presented at the Indianapolis meeting a report through its chairman, Dr. J. Lewis Howe, affirming the validity of the name and symbol columbium, Cb; and,

WHEREAS this report was accepted and adopted by this section; and,

WHEREAS the Committee on Inorganic Nomenclature of the International Association of Chemical Societies has reported on September 22, 1913, favoring the name and symbol niobium, Nb, for the element which was named columbium by its discoverer; and,

WHEREAS a later detailed investigation of the historical record by Dr. F. W. Clarke, a copy of the results of which is filed herewith,¹ finds no valid reason for the use of the name niobium;

Therefore be it resolved that we reaffirm our endorsement of the report of the committee of this section and view with regret this action of the committee of the International Association of Chemical Societies in advocating the use of the later name, thus introducing confusion where simplicity is sought.

Following this a vote of thanks, proposed by Professor Brackett and carried unanimously was accorded to the authorities of the University of Virginia, and in particular to Professor F. P. Dunnigton, for their courtesy in allowing samples from their collection of the explosive materials used by the Confederacy during the War to be forwarded to Atlanta for use as illustrative material for Professor Munroe's lecture.

The Cause of Osmotic Pressure: W. V. METCALF.

After summarizing the different theories which have been advanced, the author presented a statement and defense of Le Blanc's theory, which, though the best explanation yet offered, has up to this time not attracted as much general attention as it deserves. On this theory osmosis is considered to result from the different internal pressures of solution and solvent, the internal pressure being the resultant of the normal components of the unbalanced molecular attractions at the free surface of the liquid.

Some Possibilities of Georgia Clays: CHARLES L. PARSONS.

In the state of Georgia all kinds of clays are to be found, so that there is no reason why all sorts of clay products should not be manufactured

¹ This has already appeared in *SCIENCE*, 39, 139-140 (1914).

there. Three kinds are of especial importance: the bauxite deposits, fuller's earth, and highly aluminous clays suitable for high refractories; all are of better quality than is commonly found elsewhere, and only require proper technical investigation and control to insure their successful commercial utilization.

Permeability Measurements as an Aid in Proximate Organic Analysis: A. M. MUCKENFUSS.

A general discussion of a method of measuring the relative permeability of films (e. g., of paint or oil) to water vapor, and of the usefulness of such results as an aid in characterizing the film or membrane. The apparatus and method have been described previously.¹ As an example of the results obtainable, curves illustrating the effect of the presence of menhaden, tung or corn oil in films of linseed oil were shown.

Manufacture of Carbon Dioxide and Its Incorporation into Water: W. P. HEATH.

For the production of carbon dioxide on a commercial scale five methods are employed; most usually it is done either by combustion of coke in a special furnace, or by the action of acid on marble or dolomitic limestone. Some anomalous effects have been observed in the behavior of aerated waters as ordinarily made—for instance, that the pressure inside a freshly charged bottle may increase considerably; these effects are attributed to admixture of air with the carbon dioxide.

Walnut Stain in the Killing of Fish: G. P. SHINGLER.

Green walnuts or oak bark thrown into water will kill fish very quickly. Investigation of this question showed that in either case both narcotin and tannin are present in the solution and indicated that the latter is the active poisonous agent.

Sanitary Water Analysis in Relation to Public Health: RAY C. WERNER.

A plea for the importance of thorough control of water supplies, for the need of education in regard to this matter, and for effective inspection of filtration plants, together with regular tests—both chemical and bacteriological—of the water as delivered to the consumer.

Cotton Seed Meal as a Possible Food for Man: C. A. WELLS.

A general discussion of the possible utilization of cotton seed meal as a food for man, of its digestibility and toxicity, and of its food value, especially with regard to its cheapness as a source of protein.

Studies of the Chemical Composition of Cotton Seed: C. L. HARE.

A record of work at the Alabama Experiment Station which was undertaken in order to ascertain whether it would be possible by breeding cotton to improve the seed in the direction of a larger oil content and higher protein content, though of course without prejudice to the amount and quality of the fiber; but up to the present little definite progress has been made. Apparently there is no relation between the amount of lint and that of oil or protein; but the amount of oil seems to bear some relation to the weight of the seeds, to the percentage of protein, and, possibly, to the amount of inorganic constituents.

Occurrence and Composition of Some Alabama Phosphates: B. B. ROSS.

Large quantities of phosphate-bearing strata are found in Alabama, apparently closely associated with a thick bed of rotten limestone and with green sands; their formation is ascribed to a leaching of this phosphatic limestone. This view is confirmed by analyses of boulders, which showed that the weathered layers contain considerably less phosphate than the unweathered portion. Much of this phosphate deposit could not be worked economically at the present time, but it may be capable of later development when other fields become partly exhausted. The green sands contain both potash and phosphate, and many possess local value as a fertilizer.

Rubber Substitute from the Holly: CHARLES P. FOX.

According to a recent French invention a rubber substitute may be made from the holly. Similar experiments with American holly showed that the amount of extract is too small to be remunerative; further, that addition of this extract to reclaimed rubber delays vulcanization, increases the elongation and permanent set, but does not increase its tensile strength.

Mexican Petroleum: MORRIS O. GOTTLIEB.

Chemistry in Relation to the Development of the Fertilizer Industry: J. S. BROGDON.

An Incompatibility in Fertilizer Mining: T. E. KEITT.

When basic slag is mixed with muriate of potash or kainit a large proportion of the potash becomes insoluble in water. The insoluble compound thus formed is very slightly soluble in neutral am-

¹ *J. Ind. Eng. Chem.*, July, 1912.

monium citrate of sp. gr. 1.09, and only slightly soluble in citric acid, but is readily soluble in hydrochloric acid of sp. gr. 1.115.

Two Partially Compensating Sources of Error in the Official Method of Determining Potash: T. E. KEITT.

In the official method there are two sources of error, one the diminished volume due to precipitation of the iron, alumina and tri-calcium phosphate when ammonia and ammonium oxalate are added to the solution after boiling; the second due to occlusion of potash by the above precipitate.

An Odd Result in the Chemical Analysis of a Potable Water: F. P. DUNNINGTON.

Analysis of the water from a newly bored well showed astonishingly high amounts of nitrates, nitrites and chlorides, even after the well had been pumped dry twice. A full explanation lies in the circumstance that the party boring the well wound up by exploding a charge of dynamite "to open up crevices for water" and then to ensure a good job, put some salt in the well. In cleaning out wells some people complete the work by putting salt or lime into the well—an ill-advised custom, frequently encountered in certain regions.

In addition to the above papers there were two informal talks: one by Dr. C. L. Parsons on the radium situation and the capabilities of radium in the cure of cancer, the second by Dr. R. K. Duncan, who described the general organization of the scheme of fellowships in industrial research and recounted a number of the problems upon which the men working under this scheme are engaged; both of these talks were very interesting, and impressed those who heard them.

JOHN JOHNSTON,
Secretary of Section C

AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE

SECTION F—ZOOLOGY

SECTION F—Zoology—of the American Association for the Advancement of Science held its convocation week meeting in the histological building of the Atlanta Medical College, Atlanta, Ga., December 29 and 30, 1913.

Professor Frank R. Lillie, of the University of Chicago, was elected vice-president and chairman of the section for the ensuing year. C. C. Nutting, Iowa University, was chosen member of the General Committee of the association; Herbert Os-

born, Ohio State University, was elected a member of the sectional committee (for 5 years), and E. W. Gudger, Normal College of North Carolina, was made a member of the council of the association.

The following papers were presented at the meeting, either in full or by title:

The Behavior of Leeches with Especial Reference to its Modifiability: WILSON GEE.

The first section of the work reviewed in this paper deals with the reactions of leeches to various classes of stimuli, such as light, chemicals, contact, currents, etc. The second section is an attempt to present, so far as possible, a causal explanation of the modified behavior described in the nephelid leech, *Dina microstoma* Moore. The different responses to the same stimulus were shown in their essential features to be in accord with our knowledge of reflex-arc structure and what might be expected of its conductivity in the various stages of excitement of the leech. Acclimatization to slight stimuli, such as shadows and shocks, was explained on the basis of the dulled sensibility of the receptors and slight changes in the nerve centers involved. It was shown that the phenomenon of fatigue in the leech possesses the same fundamental characteristics as fatigue in skeletal muscle. An important factor in explaining the behavior of the leech at a given moment was shown to be the consideration of the concurrent stimuli operative at that moment. Perhaps intermediate metabolic products are the cause of much of the difference in responsiveness between normal and well-fed leeches. The increased irritability of starved leeches is probably due to much the same cause.

Additional Data on Some of Eisen's Species of Lumbricidae: FRANK SMITH.

Eisen in 1874 published a list of *Lumbricidae* from Niagara and from Mt. Lebanon, New England, in which he described four new species. One of them is the widely distributed and well-known *Helodrilus parvus*. The other three species have not been reported since. Eisen gave only brief descriptions of their external characters and their real status has been uncertain. The United States National Museum has specimens of each of these three species which were given by Eisen many years ago, and are accompanied by labels showing that they were part of the original collections on which the descriptions were based. They are in the collections of *Oligochæta* which have been turned over to the writer for study. Sections have

been made and some of the more important facts of their internal anatomy determined. With the permission of the Secretary of the Smithsonian Institution, I make known some of the results of this preliminary study. *Helodrilus tenuis* has paired sperm sacs in XI. and XII. only, and has no spermathecae. It belongs to the *Bimastus* section of the genus and is the same as *H. constrictus* (Rosa), described in 1884. Its relation to *H. norvegicus* (Eisen) is as yet uncertain. *H. tumidus* has sperm sacs in XI. and XII. only, and has no spermathecae and hence belongs to the *Bimastus* section of the genus as has been assumed by Michaelsen. *Tetragonura pupa*, now regarded by Michaelsen as simply a form of *Helodrilus tetradrus* (Savigny), is represented in the collection by a single specimen which, although labeled by Eisen as *Tetragonura pupa*, has spermiducal pores on XI. instead of on XII., as described by him. All of the reproductive organs and the crop and gizzard are four somites anterior to the position normal for Lumbricidae. There is but one pair of "hearts" and they are in VII. The entire anatomy of this specimen is that which might be expected if a specimen of *Helodrilus tetradrus hercynia* (Michaelsen) had lost the anterior nine somites and regenerated the usual number of five new ones. We do not know how many specimens Eisen may have had and it is certainly unsafe to assume that his description was based on this particular specimen. The real status of this species seems as uncertain as before. (These results will appear later under a different title in a more extended paper from the United States National Museum.)

A Study in Strongyloid Parasites of Cattle and Sheep in South Carolina: A. F. CONRAD.

Among the nematode parasites occurring in the digestive tracts of young cattle and sheep in South Carolina, the stomach worm, *Hæmonchus contortus* and the hookworm of cattle, *Monodontus phlebotomus* are very important. An extended study of these parasites was made covering a period of several years. The stomach worm occurs in both young cattle and sheep in injurious numbers. Hookworm has not been found injurious in sheep, but among cattle this is a species to be reckoned with. The life history of the two species is very similar. The eggs are laid in the stomach and after passing from the animal hatch in from three days to several weeks, depending on the temperature. In our work the stomach worm was almost altogether confined to

the fourth stomach, while the hookworm was confined to the upper eight feet of the intestines. While the hookworm fastens itself to the intestinal wall and sucks blood, we were unable to prove this in case of the stomach worm. These occur in the mucous secretion between the mucous membrane of the stomach and the ingesta and are very rarely attached. Even when the specimen is attached it is but feebly so and can be removed, while in the case of the hookworm often the head is torn off when trying to remove it with the forceps. A vulnerable point in the control of both species lies in the fact that moisture is absolutely necessary for the egg and young larval development. This is true in the laboratory, and experiments in the field have shown that this point can be taken advantage of. A heavily infested lot being about one half creek bottom and one half hillside was divided so as to separate the lowlands from the highlands. An equal number of calves of the same age were placed on these lots in the early spring and these animals received the same amount and kind of feed, except that those in the lower lot obtained their water from a running brook. At the end of the season we had 62½ per cent. more calves on the upland than on the lowland. The following year all calves were kept on the upland and no death occurred. In our work the heaviest egg record occurs during June and July, while the death rate begins the latter part of August and continues through September and October. In our work no young calves born after August 25 took the disease, while the parasites left infested animals at from ten to fourteen months of age.

On the Whale Shark, Rhineodon typus: F. W. GUDGER.

The Eruption of the Permanent Teeth: ROBERT BENNETT BEAN.

Data for 2,221 school children. The eruption of the permanent teeth in the Filipinos is from one to four years earlier than in the Germans and Americans; females are more precocious than the males in all three groups. The lower permanent teeth erupt before the upper ones, except that the upper premolars erupt before the lower.

The teeth erupt in the following order: (1) Lower first molars; (2) lower median incisors; (3) upper first molars; (4) upper median incisors; (5) lower lateral incisors; (6) upper lateral incisors; (7) upper median premolars; (8) lower canines; (9) lower median premolars; (10) upper lateral premolars; (11) upper canines; (12)

lower lateral premolars; (13) lower second molars; (14) upper second molars; (15) lower third molars; (16) upper third molars.

The law of eruption is as follows: There are one or more periods of acceleration alternating with periods of retardation in the development of any one of the structures of the body. The periods of acceleration in the development of one structure may be synchronous with the periods of retardation in the development of another structure. Thus the period of the first six months after birth is one of rapid growth of the body in length, and this is followed by a period of comparative rest of the body while the eruption of the temporary teeth is taking place, all of which are through the gums by the end of the third year. This activity in dental growth is followed by a period of rest. Following this there is a second period of rapid growth in stature, subsequent to which the permanent teeth begin to erupt, after which the growth of the body is again accelerated, to be followed by a second rapid eruption of the permanent teeth and then another rapid growth of the body which is succeeded by puberty. The temporary teeth of the Americans are worse than those of the Filipinos which are worse than those of the Germans. The girls have worse teeth than the boys in all groups. The eruption of the teeth is one of the most exact means of determining the relative development of the individual and may be used as a physiological standard to determine the relative development.

Some Curious Parasites, Commensals, etc., Found on Alcyonaria: C. C. NUTTING.

1. Discussion of the meaning of terms used to indicate the associations of animals discussed in the paper, and the analogies found in the *Alcyonaria* to plants.

2. Commensals found on *Alcyonaria*. (a) Those which are apparently harmless and do not modify the structure of the hosts. Illustrated by basketfish, serpent stars and mollusks. Similarity in colors to the hosts. Possible advantage of association to commensals. (b) Those which directly modify the structure of the host, but do not subsist upon its tissues. A genus (*Calyptrinus*) founded on such modification. *Stenella helminthophora*, in which the scale-like spicules have been remarkably modified to form a refuge for an annelid. *Calyptrhophora ijime*, in which a web-like membrane including numerous spicules is formed by an annelid. *Echinogorgia pseudosasapo*, in which a barnacle has produced gall-like swellings in which it finds protection. *Solen-*

caulon, in which it is claimed the leaves are modified to form arcade-like retreats for a macrouran crustacean, and, in another case, a brachyuran. (c) True parasites, apparently subsisting in part or in whole on the tissues of the host. *Chrysogorgia arborescens* with polyp bodies enormously enlarged by a parasitic crustacean of degraded type. *Suberia excavata*, in which the axis cylinder is extensively tunneled by a bivalve, and in which a degenerate annelid has also been found. (d) Parasites which do not live upon the tissues of the host, but which destroy it by strangulation. Millipores entirely covering an alcyonarian colony. Colonial anemones entirely covering a colony of *Caligorgia gilberti*.

An Experimental Comparative Study of the Behavior of the Animals of Two Aquatic Animal Communities: VICTOR E. SHELFORD.

The rapids and pool communities have been compared. The rapids community is characterized as *positive to strong current* and *negative to sand bottom*, while reaction to light, contact and gravitation are in accord with the position in which the animals live, *i. e.*, whether *on*, *under* or *among* stones. The pool community is *positive to sand bottom*, but only in part positive to current. It differs from the pool community in reactions to all the factors used. Those animals that are positive to current have a different optimum, hence animal communities differ in their behavior reactions.

Are the Preotic Myotomes of the Vertebrate Head Postotic in Origin? H. V. NEAL.

The assumption of an exogenous origin of the otic region by Fürbringer ('98) and for both postotic and preotic regions by McMurrich ('12)—appears untenable in the light of the evidence. As pointed out by Johnston ('05) Fürbringer's inferences appear fallacious as a result of his failure to appreciate the relations of the nerve components in the occipital region. The main support for McMurrich's conclusions is therefore rendered doubtful. While the relations of the posterior rectus muscle of the eye to a postotic nerve—the abducens—might appear to favor the postotic derivation of that muscle, the relations of the remaining eye-muscles to nerves having preotic niduli do not support this opinion. Moreover, if McMurrich's assumption were true, it would appear necessary to assume the migration of somatic motor niduli from postotic into a preotic position and the associated migration of the mandibular and hyoid arches with which the myo-

tomes of the eye muscles are connected. The discovery of Van Wijhe's ('82) somites in Cyclostomes (Koltzoff '02) and of a similar mesodermic segmentation in the preotic region of bony fishes (Boecke '04) and of reptiles (Filatoff '07) taken in conjunction with the evidence of their presence in Amphibia (Miss Platt '97) and the repeated confirmation of their existence in Selachian embryos by Hoffmann ('94), Neal ('96, '97), Sewertzoff ('98) and Johnston ('09) attests not only the presence of a primary preotic segmentation, but also indicates that the mesodermic segmentation, as in *Amphioxus*, is continuous from the preoral region backwards through head and trunk. The recent rehabilitation of *Amphioxus* by Delsman ('13) as a transition form between annelids and vertebrates is symptomatic of the recent trend of morphological opinion. A fuller discussion of the problem will be given in a forthcoming number of *The Journal of Morphology*.

The Story of Human Lineage (vice-presidential address): WILLIAM A. LOCY.

Microscopic Demonstration of Fecal Contamination of Food, as Evidenced by the Presence of Protozoan Spores: C. W. STILES.

Instruction of Young People in Respect to Sex: T. W. GALLOWAY.

In a brief discussion like this some things must be assumed. Among these things we may mention the following: (1) Reproduction and sex, next to hunger and the need of food, is the most profoundly influential factor in human life. It is basal to society and to particular organization of society. (2) Anything which bulks as large in human life as sex can not be unimportant in education. (3) Its greatest meaning in education is not in connection with its abuses, perversions and dangers, but rather in the normal, wholesome and constructive contribution which it makes to health,—physical, mental, social, moral and religious. (4) Consequently sex instruction means not emphasis of the pathology of sex, but of the normal development of human personality and society because of, and by means of, the impulses growing out of sex. It deals with cleanness, purity, marriage, home, fatherhood, motherhood, children, parental care, chivalry and the like. (5) In the normal human child there is no such thing as ignorance and innocence with respect to matters of sex. The only choice we have is whether the information will be clean and correct and free from vile and vulgar connotations, or will be incomplete, sug-

gestive and curiosity-inspiring. (6) Even if we could keep children ignorant, there is in the long run no positive correlation between ignorance in respect to vital and far-reaching phenomena and safe, wise adjustment to these phenomena. There is, however, a correlation between knowledge and right conduct, howbeit the correlation is not 100 per cent. (7) We must, therefore, have from some source, adequate instruction in respect to matters of sex. (8) We all agree that their instruction ought to come from parents and others similarly related to the child. (9) We know, however, that this is not being done by the present generation of parents in any serious degree. We know, furthermore, that the present-day parent is not fitted to do it properly. (10) We need, therefore, to prepare a generation of parents who can do this work for society. This must be done by social agencies outside the family. (11) Colleges and normal schools are in position to do two things for the people coming to them: (a) They may give the kind of instruction which parents ought to have; and (b) they may train future teachers in a fundamental knowledge of these matters so that they may bring help to the present-day generation of parents—through parent-teacher associations in the interest of the child.

The discussion of Professor Galloway's paper was led by Professor E. B. Wilson, of Columbia University, and was participated in by several members of Section F.

Variation in Oxyurias: Its Bearing on the Value of a "Nematode Formula": STANLEY B. FRACKER.

Owing to the difficulty of classifying Nematoda certain writers have used a "nematode formula" in their descriptions. This formula shows the proportions of the body structures of the individual worm described. The investigation which this paper reported consisted of the measurement of a large number of individuals of *Oxyurias vermicularis* Linn. to determine the variation in the species. The range proved sufficiently great to throw doubt upon the value of a formula. The conclusion was reached that while the general proportions of the organs of a round worm have a taxonomic importance, the formula as it has been used is likely to be more misleading than valuable. The full paper is to be published soon.

The Development of the Olfactory Nerve and Its Associated Ganglion in Lepidosteus: CHAS. BROOKOVER.

The olfactory nerve and the nervus terminalis

has been followed in its developmental history in a graded series of embryos and larval fishes to the adult condition. The olfactory nerve and the nervus terminalis are interpreted as arising together from the ectodermal nasal placode in the same way as was previously found in *Amia* and *Ameiurus*. The ganglion of the nervus terminalis can not be recognized with certainty until a late embryological stage (about 100 hours from fertilization) and later is divided into a compact central ganglion and a more diffuse peripheral ganglion in or near the nasal capsule. In the adult fish the central ganglion is located on the ventral side of the olfactory nerve anterior to the masticating muscles about an inch rostral of the brain. It can not be positively stated that there is fibrous connection with the other cranial nerves, but a large ramus of the fifth nerve runs in the same bony channel. We have recently found more than two hundred large ganglion cells associated with the olfactory fila in adult man that have been interpreted as belonging to the nervus terminalis. Full paper to be published in *Journal of Comparative Neurology and Psychology*.

The Library of Congress as an Aid to Scientific Research: E. W. GUDGER.

The Library of Congress, the national library in fact if not in name, contains about 2,000,000 books, including the priceless Smithsonian Collection, and is the richest depository of the kind in the new world. These books, including sets of scientific periodicals and proceedings of learned societies, are, under very liberal regulations and restrictions, available for the use of those doing serious scientific research work anywhere in the United States. Further, the library maintains a division of bibliography the services of which are available to the research worker for the settling of bibliographical questions, for perfecting incomplete references, for compiling lists of references, and even for copying out brief extracts. On the other hand, to the scientific man, visiting Washington for the purpose of making use of the Library of Congress, every facility for work is accorded upon the presentation of proper credentials. He is given a room or an alcove in which to work, may even be admitted to the stacks, and if necessary may have an attendant or stenographer, while there is no limit to the number of books he may have on his table for reference. In short, it is the purpose of the librarian of congress and his associates to supply the unusual book for the unusual need, to make the national library the great-

est reference library in America, and the speaker, having during the past seven years borrowed hundreds of books from it, is able to testify that this purpose is not a matter of theoretical intention, but of actual achievement. This being the nearest large library to the South, it has seemed well, at a meeting of the American Association for the Advancement of Science, held in a southern city and attended largely by southern men, to call the attention of Section F and of the whole association to the great function of this great library.

A Demonstration of the Ears of Some White and Colored People of New Orleans, La.: ROBERT BENNETT BEAN.

During the past three years and more I have collected about 200 ears of colored people in New Orleans, and about as many more of white people, some of which are preserved at the Smithsonian Institution, and the remainder at Tulane University. I measured the ears after classifying them according to my grouping of hyper, meso and hypo forms, but I found that many of the ears of the colored people were unlike any of the three forms, and I call them negroid ears. I had previously collected the ears of Filipinos and placed them in the Smithsonian Institution, and in addition to the ears that I have collected and measured I have examined thousands of ears of Filipinos, Negroes, white people and others, therefore, I feel qualified to classify the normal ear. The ears of the white people may be grouped into three forms which will be described briefly as follows: The hypo ear is a small round ear, that has a deep concha, with a raised helix, that makes the ear look like a shallow bowl. The meso ear is large, often almost rectilinear, and somewhat flattened, and not so bowl shaped as the hypo ear. The hyper ear is long, narrow and usually small, with everted tragus, antitragus and anthelix and rolled back helix. The meso ear seems to be the form from which the others have been derived, and the hypo and hyper forms have apparently undergone a greater amount of retrograde metamorphosis than the meso ear. The three forms are found among the colored people in almost as great purity as among the white people, but the most usual condition of either form is to present a certain amount of wrinkling of the helix as if it had been shriveled, and in contracting the ear is distorted. The ear of the Negro also appears in the form described by Hrdlička, which is small, almost square and flat against the head. The ears of the colored people are, as a rule, smaller than those of the

white people, and this in connection with the wrinkled condition and the presence of the ear described by Hrdlička has led me to consider the Negro ear as having undergone a greater amount of retrograde metamorphosis than the ear of the white people, even a greater amount than the hypo or hyper forms. I am at present at work on the development of the ear of the fetus in the colored people to determine the extent of development of the ear in the early stages of fetal development in order to find the extent of retrograde metamorphosis.

The First-year Zoology Course: JOHN P. CAMPBELL.

The first-year zoology course is of special importance, for the reason that most students go no farther. It should, therefore, have the widest human interest possible, and be no more technical than is necessary, in order to give the largest returns to the greatest number. As usually conducted, this course consists of a more or less intensive study of a few types, the idea being that the benefit to be derived is directly proportional to the amount of contact with these in the laboratory. This is believed to be wrong, and the idea is urged that the amount of laboratory time should be just enough to develop a mental attitude in the student, and put him in sympathy with the methods by which the subject has been developed. If the laboratory work consists merely in verification, no amount will do this, but if it is properly conducted, this result may be reached in less time than is commonly used. Emphasis should be laid also on the historical and philosophical aspects of the subject, and for this purpose students should be required to do wide reading and make ample abstracts. Every effort should be made to have the student get a large view of nature, and he should be able to interpret as well as observe. General discussions should be introduced wherever possible. Zoology is the study of animal life, and the more contact with life is presented, the stronger is the course. Morphology in the old sense has passed away, but the more the student learns to interpret structure in terms of modification in relation to environment, the more is he likely to be mentally awakened. The order of presentation is most important and, in the writer's experience, few students are intelligently interested in the Protozoa, if they are used to introduce the course. Insects serve much better as an introductory subject, after which evolution may be taken up. If then the insects are reviewed and the re-

maining Arthropods taken up in the light of evolution, the study of the tissues in these leads logically into the Protozoa, after which the remaining phyla may be taken up in ascending order. The success of this course should be measured by the reaction of the student, and the proportion that are attracted to take the more advanced work, in which, of course, different methods should be pursued. The round-table discussion of Professor Campbell's paper was led by Professor Galloway.

The Content of a First Course in Zoology: T. W. GALLOWAY.

I. This is so conditioned by what we desire to accomplish that I want to outline briefly some of the more important things I think we should try to do for the pupil in such a course. (1) We should produce and conserve a vital interest in animals. (2) We should secure an appreciation of the human values of animals. (3) We should encourage the attitude in the student of raising and solving problems concerning animals. This means the scientific attitude and the scientific method. (4) The pupil should have some ability to use the library, the field and the laboratory in pursuit of these interests. (5) He should be able to sustain interest in such problems for considerable periods. (6) There should be some sense of the way in which organisms respond to the environing conditions; some conception of individual development, and of the evolutionary series of animals. (7) The pupil should have some knowledge of the cell and of protoplasm as basal in plant and animal life. (8) He should get some practical experience in classifying organisms. (9) He should have a conception of the place of man in the biological series, and in such a way that it will heighten rather than diminish his appreciation of the meaning of the higher human qualities. (10) We should secure for him a sane appreciation of the origin and meaning of reproduction and sex, and of its bearing on human life.

II. It follows from the above that the point of view can not be narrowly morphological. Such, or all, of the possible approaches must be used as will contribute to these ends. Morphology, physiology, ecology and distribution, classification, touches of embryology and such general questions as evolution, heredity, history of biology and the like, must be included. Morphology alone secures little more than a certain deftness of observation and expression. Only when it is enriched by the more vital aspects do we secure discrimination, and the making and testing of general conclusions. The

pupil is entitled to "follow thru" in his mental processes.

III. Life is too short for these results to be accomplished by the laboratory alone or chiefly. The value of laboratory work is not in the zoological information gained by means of it. Its chief value is to enable the pupil to appreciate how the information got into the books, to give him skill in working out things for himself, and to use the increased interest he has in handling objects rather than in reading descriptions of them. It appears to me that about one half the time should be given to laboratory and field work, with more emphasis on the latter than is usual, and one half to class room, library and museum. I conceive that very much more use should be made of the library and somewhat less than is customary of the text or the lecture.

IV. I suggest the following for guidance in the selection of forms to be used in the laboratory study. They should be from those groups that have most human meaning; that are most common in the environment of the pupil; that have fewest disagreeable and repelling points; that illustrate best the great underlying processes and relations which we desire the pupil to get. Such a course might very appropriately emphasize the Protozoa, the Worms, the Mollusks, the Arthropods and the Vertebrates, in the laboratory and the field. The library and the museum may very well supply such synoptic view of the other groups as is needed in the first course.

It is quite difficult but quite important to remember that we are concerned to develop human beings and not in a mere logical display of zoological material. There is no necessary correlation between the two processes.

Note on the Present Status of the Gipsy Moth Parasites in New England: L. O. HOWARD.

Some Notes Regarding the Natural History of the Mole Cricket: E. L. WORSHAM.

The Jassidæ of Maine and their Bearing on the Distribution of this Group in America: HERBERT OSBORN.

Collections during the summer of 1913 greatly extend the records of the species in this family for Maine. For the most part these simply extend known range from adjacent localities, but in some cases from such distant points as Michigan, Iowa and even the Rocky Mountain region.

TUFTS COLLEGE, MASS.

SOCIETIES AND ACADEMIES

THE AMERICAN PHYSICAL SOCIETY

A REGULAR meeting of the Physical Society was held at Columbia University, New York, on February 28, when the program was as follows:

"Radiation Constants of a Nitrogen-filled Tungsten Lamp," by W. W. Coblenz.

"The Villari Critical Point in Ferromagnetic Substances," by S. R. Williams.

"Motion of a Radiating Oscillator," by E. B. Wilson.

"A Method of Rapidly Extracting, Purifying and Compressing Radium Emanation," by William Duane.

"On the Asymmetric Distribution of Velocities of Photo-electrons from Platinum Cathode Films," by Otto Stuhlmann, Jr.

"On the Density of Radiant Action," by William Duane.

"Secondary Electron Emissions from a Hot Cathode Caused by Positive Ion Bombardment," by Irving Langmuir.

A. D. COLE,
Secretary

THE AMERICAN PSYCHOLOGICAL SOCIETY

THE New York Branch of the American Psychological Association met in conjunction with the Section of Anthropology and Psychology of the New York Academy of Sciences, at Princeton, on February 23. The program was as follows:

"Some Tests of Efficiency in Telephone Operators," by Dr. H. C. McComas.

"Transfer and Inference in the Substitution Test," by Professor H. A. Ruger.

"A Comparison of the Effects of Strychnine and Caffeine on Mental and Motor Efficiency," by Dr. A. T. Poffenberger.

"A Comparison of Stylus and Key in the Tapping Test," by Dr. H. L. Hollingworth.

Inspection of the Psychological Laboratory of Princeton, and informal reports of work in progress.

"An Experimental Critique of the Binet-Simon Scale," by Carl C. Brigham.

"The Work Curve for Short Periods of Intense Application," by Professor R. S. Woodworth.

"Recall in Relation to Retention," by Dr. Garry C. Myers.

H. L. HOLLINGWORTH,
Secretary

"THE CAMERA OF QUALITY"

POLYGON CAMERAS

with

Rietzschel Double Anastigmats

are the embodiment of all that is desirable in cameras. They are compact, small, and light in weight, yet they are very reasonable in price: "They fit the Pocket." They are made from **miniature** size up to 5×7 inches, in all styles. All are built of light but indestructible metal; all are leather covered; all have leather bellows; all have rising, falling and cross front; all have detachable lensboard; all have quickly reversible ground glass; all are fitted with double anastigmats, the better ones with the finest cemented lenses ever put on the market, in compound shutter.

We also sell

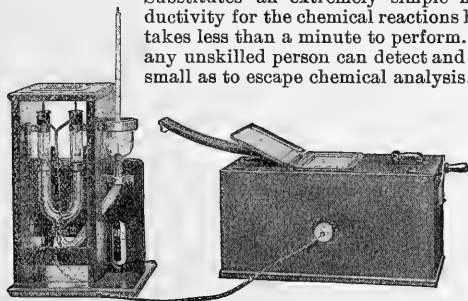

ERNEMANN Cameras and Double Anastigmats

MEYER CAMERA & INSTRUMENT CO., Inc.

18 West 27th Street, NEW YORK

IMPORTERS OF AND DEALERS IN SCIENTIFIC INSTRUMENTS

DIONIC WATER TESTER

Substitutes an extremely simple measurement of electrical conductivity for the chemical reactions hitherto employed. Entire test takes less than a minute to perform. By the use of this apparatus, any unskilled person can detect and measure traces of impurities so small as to escape chemical analysis. It has been found useful for measuring slight traces of impurities in distilled water, sewage pollution in rivers, the hardness of water, etc. When it is desired to know how much of a known substance is present in water, the Dionic Tester gives the answer with a rapidity and simplicity unapproached by any other method.

an Introduction to Microscopic Methods and to Histology, by SIMON HENRY GAGE of Cornell University. The 11th edition has eight pages of new matter and corrections, otherwise it is like the 10th ed. Price \$2.00 postpaid.

COMSTOCK PUBLISHING CO., Ithaca, N. Y.

Mathematical Monographs

A Series of Volumes, each independent of the others, on topics in pure and applied Mathematics

Edited by MANSFIELD MERRIMAN and ROBERT S. WOODWARD

6x9 inches. Cloth, \$1.00 each

The latest addition to this Series is No. 12, entitled

The Theory of Relativity

By ROBERT D. CARMICHAEL, Associate Professor of Mathematics, Indiana University.

The following is an extract from a two column review which appeared in Science, February 13, 1914:

"Unlike most presentations of the theory of relativity, which contain a considerable amount of technical mathematical physics, Carmichael's is non-technical and logical in the same way that the discussion of the foundation principles of geometry or mechanics or chemistry might be made non-technical and logical. The book may, therefore, be read with ease by the mathematician who has little or no knowledge of modern physics or by the physicist who is unacquainted with mathematical analysis."

Descriptive literature of this series upon request.

RECENT BOOKS

Animal Communities in Temperate America, as Illustrated in the Chicago Region. By VICTOR E. SHELFORD, Instructor in Zoölogy in the University of Chicago.

This volume by Dr. Shelford presents the principles of field ecology, illustrated by the more widely distributed animal habitats of the eastern half of temperate North America, and the aquatic habitats of a much larger territory. Six chapters deal with general principles.

In several chapters the animal communities of lakes, streams, swamps, forests, prairies, and various soils and topographic situations are considered from the point of view of modern dynamic ecology. A very valuable feature of the book is the three hundred figures of widely distributed animals chosen to represent the chief types of animal communities and their characteristic modes of life.

380 pages, 8vo, cloth; price \$3.00 (weight 44 oz.).

Artificial Parthenogenesis and Fertilization. By JACQUES LOEB, Head of the Department of Experimental Biology, Rockefeller Institute for Medical Research.

This new work presents the first complete treatment of the subject of artificial parthenogenesis in English. Professor Loeb published four years ago a book in German under the title *Die chemische Entwicklungserregung des tierischen Eies*. Mr. W. O. R. King, of the University of Leeds, England, translated the book into English, and the translation has been revised, enlarged, and brought up to date by Professor Loeb. It gives, as the author says in the preface, an account of the various methods by which unfertilized eggs can be caused to develop by physico-chemical means, and the conclusions which can be drawn from them concerning the mechanism by which the spermatozoon induces development. Since the problem of fertilization is intimately connected with so many different problems of physiology and pathology, the bearing of the facts recorded and discussed in the book goes beyond the special problem indicated by the title.

318 pages, 12mo, cloth; price \$2.50 (weight 36 oz.).

Walker Prizes in Natural History

By the provisions of the will of the late Dr. William Johnson Walker two prizes are annually offered by the BOSTON SOCIETY OF NATURAL HISTORY for the best memoirs written in the English language, on subjects proposed by a Committee appointed by the Council.

For the best memoir presented a prize of sixty dollars may be awarded; if, however, the memoir be one of marked merit, the amount may be increased to one hundred dollars, at the discretion of the Committee.

For the next best memoir a prize not exceeding fifty dollars may be awarded.

Prizes will not be awarded unless the memoirs presented are of adequate merit.

The competition for these prizes is not restricted, but is open to all.

Attention is especially called to the following points:—

1. In all cases the memoirs are to be based on a considerable body of original and unpublished work, accompanied by a general review of the literature of the subject.

2. Anything in the memoir which shall furnish proof of the identity of the author shall be considered as debaring the essay from competition.

3. Although the awards will be based on their intrinsic merits, preference may be given to memoirs bearing evidence of having been prepared with special reference to competition for these prizes.

4. Each memoir must be accompanied by a sealed envelope enclosing the author's name and superscribed with a motto corresponding to one borne by the manuscript, and must be in the hands of the Secretary on or before April 1st of the year for which the prize is offered.

5. The Society assumes no responsibility for publication of manuscripts submitted, and publication should not be made before the Annual Meeting of the Society in May.

Subjects for 1914 and 1915:—

Any biological or geological subject.

GLOVER M. ALLEN,

Secretary.

THE AMERICAN SOCIETY OF NATURALISTS SYMPOSIUM ON THE SCOPE OF BIOLOGICAL TEACHING IN RELATION TO NEW FIELDS OF DISCOVERY FROM THE STANDPOINT OF A ZOOLOGIST

THE speaker must admit that upon taking time to reflect on the various ramifications of the subject announced his first reaction was one of wonder at himself for ever having agreed to enter into such a discussion; for obviously any statement must be the expression of a personal opinion influenced largely by the advocate's own training and the conditions which obtain in his local institution.

Upon roll-call one finds oneself confronted by such lusty newcomers as: ecology, animal behavior, comparative and general physiology, biochemistry, cytology, genetics, biometry, which, however, is really a method of work and not a special field of investigation; experimental zoology, a sort of general mélange which also includes some of the more special fields enumerated; experimental embryology, a subject inextricably interwoven with experimental cytology and which in recent times has sported a new offshoot—tissue-culture in vitro—already almost an ology in itself; not to omit such important applied subjects as parasitology, protozoology and the application of biological principles to human problems.

How much are we justified in letting these replace our traditional general zoology, invertebrate zoology, comparative anatomy of the vertebrates, histology and embryology? One realizes vividly the just merits of the new claimants, but when he faces the problem of deciding as to which

of the older subjects they shall supplant, he can not but hesitate. Which of these true and tried teething-rings of our zoological infancy shall be discarded? Can we spare any of them? I must confess that after considerable pondering I have concluded that for the training of the professional zoologist or the teacher of zoology I do not see how we can. I can find ways for shortening them to make room for new subjects and ways for injecting new meanings into them from our late fields of discovery, but it seems to me that when all is said and done, comparative morphology, including embryology, together with some histology, is a well-nigh indispensable ballast for our ship of biological progress. None of the newer experimental lines can yet take the place of these for training the zoological apprentice. I have yet to find the subjects in which I can pin my students down to exact observations, unequivocal inference and far-reaching generalizations in the concentrated form I can secure in a course of study based on morphology, but saturated throughout with demands for interpretation of the structures under consideration in terms of function and environment.

It seems to me, moreover, that nearly all of these newer lines actually or tacitly presuppose a considerable amount of systematic or morphological training. Much of our experimental zoology has bearings on the problems of evolution; hence what can such work mean to a student who has not reached an understanding of organic evolution from a careful comparative study of animals of different degrees of complexity? Or of what avail are many of the efforts of our statistical friends, the biometricians, without a keen appreciation on our part of the questions at issue, based fundamentally on an understanding of the real significance of variations? Or in the realm of animal behavior, one of the insistent new

claimants for attention, the facts have meaning mainly as interpreted from the comparative or the evolutionary point of view, which presupposes knowledge of the relative complexities of the fundamental types of nervous systems. Of what significance, for example, is Professor Jennings's trained starfish, except as understood in terms of our knowledge of the starfish nervous system and the animal's relative position in the animal kingdom?

Or, taking the field of experimental embryology, how far should we get in true scientific appreciation of the recent work on tissue culture *in vitro* had we not considerable preliminary familiarity, not only with the structural nature of tissues but with general embryology as well? And when it comes to the quest for organ-forming substances, cytoplasmic prelocalizations or whatever we may be disposed to call pre-cleavage differentiation, certainly the neophyte can travel the road towards understanding but a short distance without considerable preliminary knowledge of organogeny and even of cytology. Or again, in the field of genetics, while some of the practical values may be understood and utilized by those having meager knowledge of other biological facts, the full appreciation of the new discoveries can be grasped only by the well-rounded student, conversant with modern points of view in the fields of variation and evolution, embryology, cytology and general zoology.

Coming to cytology, no one, I think, will gainsay the statement that it is highly desirable for students to have had preliminary courses in comparative zoology, histology and embryology, to say nothing of a grasp of the problems of heredity and variation.

At the very outset of our planning, of course, we are met with the question, which of our students are we planning for? The five or ten per cent. who may become pro-

fessional zoologists, the somewhat larger proportion who are going into medicine, or the vastly greater proportion who are going to take only one, or, at most, two or three courses as part of their general education? Personally, after experimenting with various plans for different classes of students, I have reached the rather settled conviction that no matter what the later work of the students is to be, they may all profitably be subjected to the same first-year course; namely, a course which will give them a good perspective of the whole field of zoology, old and new, and which emphasizes general principles rather than morphological detail, though by no means ignoring the essentials of morphology, or in other words, a course arranged for principles and not primarily for types.

I think there is particular danger of the specialist letting his specialty obsess him to the disadvantage of his general introductory course. Even though facts are formally true in themselves, the student may be given an entirely erroneous view of the whole, if the facts emphasized are the less important components. To an entomologist all zoology may lie in the realm of the insect, or perhaps of even some particular group of insects; or, if a specialist in fungi, all botany centers, perhaps, in the toadstool and its anemic brethren; or if a cytologist, the student may hardly be led to realize that there may be something in the world of life worth studying that does not lie under a cover-slip. I thoroughly sympathize with the heartfelt cry that heads the title-page of a recent elementary text-book in botany, "More about hay, less about karyokinesis!"

The general course I have in mind, though omitting much of the technical detail that a professional zoologist must acquire, nevertheless should give the prospective specialist such an orientation in the

whole field of his science as is almost indispensable for balance and which in all probability he will not get in any of his later courses. At the same time it must give the general student an intelligent insight into the real live problems of zoology and should tempt him to venture further into some of the special phases of the work which appeal to him. The laboratory work of this introductory course should, in my estimation, be a study of various animals in all their life relations, with a constant demand on the student for interpretation, not merely corroboration of anatomical and morphological descriptions. The forms should be selected to illustrate general principles of physiology, environmental relations, evolution and genetics as well as phylogenetic position. They should also introduce the student to the fields of embryology and histology. In our own university we have found a series consisting of the frog, ameba, paramecium, euglena, volvox, hydra, gonionemus, crayfish and bee to answer our purposes very well as an introduction to general principles in a one-semester course, although we prefer to have our students take a second semester of zoology supplementing the general work by additional forms taken partly from the same but mainly from other phyla of the animal kingdom.

The frog is admirably adapted to the elucidation of general principles of morphology, physiology and ecology, and also furnishes excellent material for an introduction to embryology and histology. In our own laboratory we devote a total of some fifty-six hours of work to the frog. We find it a decided advantage to begin with a form sufficiently large that every student can get to work on it during the first ten minutes of the first laboratory period. Having begun with a larger form, all will not come to the microscopical work

and require assistance at the same time. The transition from the histology of the frog to the amœba is a simple one, and in the succeeding series of forms we get not only more or less of a gradational morphological sequence which will give the student some idea of evolutionary progress, but a good series for the introduction of the ideas of animal behavior, differences between plants and animals and other fundamental problems. For instance, in *volvox* we see the beginnings of the body as distinct from the germ, and it affords a splendid opportunity for introducing ideas relative to germinal continuity, evolution of sex and the like. *Hydra* and *Gonionemus*, besides opening the way for the conception of metagenesis, illustrate the simpler principles of differentiation. The frog, crayfish and bee, when contrasted in their structural adjustments to environmental conditions, give an excellent selection for showing diverse means of meeting the same fundamental problems of existence. Lastly, the bee is excellent for guiding the student into the problems of genetics. I find that the single query in the laboratory outline as to how, inasmuch as the workers are sterile, their various characteristics are passed on to the next generation, is more serviceable in opening up to the student the real underlying problems of heredity than a considerable amount of mere lecture declamation on the subject would be.

From the first year on there will be a divergence among the students, depending upon their future intentions. Many will never get beyond the first course. On the part of general students, however, I find a strong and increasing demand for at least one or two additional courses which will afford them greater opportunity to get the bearings of biological principles on human problems. I think it can be justly urged, therefore, that this applied phase of the

work is worthy of a modest course somewhere in the departmental curriculum after the first year. If "the true study of mankind is man," certainly the most promising approach to this study is through biology. Our social and educational problems have suffered too long already at the hands of the biologically untrained. I suspect that to the great majority of our students who will never become trained zoologists there is nothing of greater value we can give them than a clear-cut biological orientation towards the problems of human life. Train such students week by week and month by month in scientific discrimination and in the handling of biological evidence secured by their own efforts at observation, and we shall contribute to society fewer victims for the demagogue, the sensationalist and the charlatan.

Of all people, the prospective teacher and the social worker need the vivid knowledge of facts concerning living things that can be gained only by direct contact with the objects themselves, yet how few of either of this class ever get more than the colorless remnants of biological truth that may be gained at second hand through the paths of pedagogy and sociology! Many professors of pedagogy and sociology are coming to realize the importance of preliminary biological training for their protégés, and, although themselves biologically untrained, are endeavoring to make good the deficiency. While one sympathizes heartily with the feeling of necessity which prompts their endeavor, he can not but marvel at some of the biological rag-time effects not infrequently served up in these fields as biological truths.

How many teachers have an adequate understanding of the functional adjustments necessary to normal activities in either simple or complex animals? Yet, lacking this, how can they be expected to

prescribe for the imperfect mental or physical adjustments of their charges, to establish habits of thought or behavior, to correct defective habits by developing compensatory ones, or to lay down guiding principles for the most efficient furtherance of normal functions?

Or, to turn to the matter of natural endowment, how many of them realize that what a child becomes is determined in great measure by its inborn capacities and that education consists largely in applying the stimuli necessary to set going these potentialities and of affording opportunity for their expression? That of the good propensities some will require merely the start, others will need to be fostered and coaxed into permanence through the stereotyping effects of proper habits; that of the dangerous or bad, some must be kept dormant by preventing certain kinds of stimulation, others repressed by the cultivation of inhibitive tendencies, and yet others smothered or excluded by substituting in their place desirable traits? And yet if they are ignorant of all this are they not pretty much in the position of one who would attempt to operate a complicated engine without any understanding of its mechanism?

In this whole matter of human heredity, or eugenics, clearly the biologist is the one to lead the way, and yet we find this field being exploited by all sorts of impossible fanatics and incompetents. In spite of the badinage of the press and the confusion resulting from its use of the term eugenics in many senses, nearly all of them equally wrong, the science itself has come to stay, and the public, sensing the vital truth at bottom of it, is going to demand more and more enlightenment. Surely if anywhere we need here to guard against the ambitious enthusiast who promises the impossible, who, for instance, at one sword thrust

would slay the demon of degeneracy and restore a sort of pristine purity to the human race. And yet how is the public to be guided aright unless biologists, the ones most competent to advise, step forward and keep them in touch with the more solid advances which are being made through the sure though unspectacular methods of research?

In our own institution I find a strong demand on the part of general students for at least an additional lecture course in genetics with emphasis on the eugenic phase. Some take the elementary embryology as a sort of laboratory course to accompany the work and it seems to me that this is a combination to be commended. I see no reason, moreover, why such students should not be encouraged to take, as many do with advantage, courses in ecology, animal behavior, elementary entomology or parasitology, according to their taste, even though they do not take the regular courses in invertebrate zoology or comparative anatomy which personally I feel are well-nigh indispensable to those who expect to teach zoology or become investigators.

But how, it may be urged, are we to find a place for the new subjects if we are still to retain our traditional courses? Will these not occupy quite all of the time that can be devoted to zoology?

One way to gain considerable time is to shorten some of these older subjects. This can be done without sacrifice of thoroughness on the part of the student, it seems to me, by dissecting fewer forms in detail and using the remaining forms largely for the study of the more significant features in which they are different. Why, for instance, have the student dissect out in minute detail the arterial system of the dog-fish, perch, necturus, turtle, pigeon and cat when a careful dissection of this system in the dog-fish, necturus and the cat, together

with a comparatively brief study of the corresponding systems in demonstration specimens of the other forms, will give him the necessary experience, knowledge and perspective to serve the full educative value of the work?

But does this advocacy of retaining the old standbys carry with it the corollary that they are to be taught in the same old way, from the same old malodorous specimens, and from the same old standpoint? By no means. There is such a thing as letting nearly all of the newer fields enter into the traditional courses to vitalize and illumine them while at the same time retaining their valuable disciplinary and informational features. We need not replace or dilute, but rather compress more of value into these courses by insisting on ecological and physiological along with the morphological and evolutionary interpretations. A frog, for example, is interesting enough as a piece of architecture, but it becomes many times more interesting when we advance to its interpretation as a machine constructed for the performance of a wide range of life activities. When the student examines our selected types of animal machines in the laboratory he should be made to realize that he is not only to interpret their respective structures as so many intergradients in an evolutionary series, but that he is also to explain the mechanism in each case in terms of function and adjustment to environment. What a given structure accomplishes and how it does it, what its efficiency is as compared with other types, is of fully as great importance as how, from the evolutionary point of view, this or that organ has advanced or regressed over the corresponding one in some other animal. Omit either kind of interpretation and the student has been deprived of valuable insight that he might have had with very little additional effort.

It may seem banal even to call attention to this obvious fact, but visit the average laboratory or look into the laboratory manuals in common use and one can not but feel that this evident fact has been almost entirely ignored.

I think there is a nearly universal feeling to-day that we have been too closely wedded to structure and have wrongly divorced it from function and environmental adjustment; our convictions, however, find but tardy expression in our manuals and laboratory directions. Part of this situation is undoubtedly due to the inertia of routine. It is much easier to realize that another system is better than actively to break with traditional texts and guides and rearrange our work in harmony with our new ideals.

Supposing that I had a free hand to arrange a curriculum for a zoological department according to my own feeling of what would turn out a well-balanced student to undertake graduate work or to become a teacher in secondary work, I should plan about as follows: a two-semester course in elementary zoology of five credit hours per semester; a one-semester course each in invertebrate zoology, comparative organology of vertebrates, embryology and histology, omitting, if anything, the histology. Into all of these I would inject as much of the living animal and of experimental processes and interpretations as was at all practicable; that is, I would have these fundamental courses morphological but shot through and through with interpretations of functions and adjustments.

Finally I should want to see offered such additional courses in animal behavior, ecology, cytology, experimental embryology, general physiology, genetics and other special subjects, as the abilities and tastes of my departmental colleagues and myself would warrant.

As for graduate students it seems to me that since they are presumably mature individuals with thorough preliminary training in the main zoological subjects, one of the important things to do is to wean them away from mere course taking, a habit with which they are usually obsessed, and head them into problems and seminars. If their preparation is inadequate let them take courses open to advanced undergraduates but strictly graduate courses can, I believe, be advantageously restricted to a few lectures per week in various special fields.

Being mature, the graduate student may well be expected to get much of his information by reading for himself. By way of suggestion I would give him a memorandum to the effect that it goes without saying that in addition to his more technical pursuits, every candidate for the doctorate will be expected to know modern evolution problems; the generally accepted views on phylogenetic relationships and the validity of the criteria on which these are based; and the elements of animal behavior, genetics and developmental mechanics. A suitable list of special references for study in these fields would be appended.

Furthermore, for the purpose of broadening his interests and cultivating a sense of proportion, each candidate might advantageously be given a list of fifty or more books that he is expected to have read before he completes his work. This list would include mainly the general classics of the subject in various departments, such as voyages, travels and explorations; history; biography; a few special memoirs; general principles; a few works of the better literary naturalists; and some of the more general works in special fields.

In conclusion I should say, then, that I see no need of abandoning our general zoology, comparative anatomy, invertebrate zoology, embryology and histology courses

in favor of the newer biological sciences, though we can perhaps advantageously shorten them to make room for courses in the new subjects and we can pervade them all more or less with the method and thought of the newer work. If in these fundamental courses we will but put life back into our laboratory specimens, life into our method of offering them as subjects for thought, and life into our students by forcing them into the interpretative attitude of mind, then I think we shall have gone far toward introducing our charges to much that is significant in the newer fields without sacrificing the well-recognized values of the older discipline.

MICHAEL F. GUYER

UNIVERSITY OF WISCONSIN

FROM THE STANDPOINT OF A BOTANIST

THOSE of us who are possessed of a conservative temperament may be inclined to look askance at the newer fields of investigation, or to doubt their value for educational purposes. If so, we need merely to consider that not many years ago science of any kind was not regarded as a suitable subject for school or college. Moreover, the sciences themselves have undergone a marked evolution. The earliest biological studies were descriptive and enumerative; then came the study of internal structure, followed in its turn by the study of function, environment and inheritance. To an outsider it looks as though the subject of entomology were still largely in the taxonomic stage of development, which is not to be wondered at when one recalls that over half the species of animals are insects.

Instruction in biology has likewise exhibited an evolution; it no longer consists wholly or even largely of systematic work. Botanists still do a certain amount of "manual labor," but fortunately we have passed out of the period when first-year

botany consisted in a study of Gray's Manual, and the second-year botany of more Gray's Manual. Botanists have traveled a long way from the ideal of Linnæus, who declared that the only worthy task of a botanist is to know all the species of the vegetable kingdom by name. Thus progress has been the word in biological teaching, but, as has been the case in education in general, fads have crept in and have usurped the place rightly belonging to less spectacular but more fundamental aspects of the subject. One of the most pernicious of these in the recent history of botanical instruction is indicated by the flood of elementary text-books on so-called practical botany, in which there is very little botany, but a good deal of elementary forestry, horticulture, plant breeding and the like.

Since all of us specialists are faddists in a more or less worthy sense, we run the risk of introducing our favorite topics into our courses, and even giving them undue prominence. Moreover, we may experiment on the matter and method of our courses, while quite alive to the danger of riding our hobby in the lecture room. It will probably be agreed that the course which is most important from the standpoint of pedagogic experiment is the introductory course—general biology or general botany or general zoology, as the case may be. In fact it may be said that the crux of the question lies here, for if it can be decided what is to be the content of this general course the more advanced courses will readily fall into line; the character of the latter will be largely determined by the special needs in the particular institution; for instance, the course in plant pathology which would be required in a college of agriculture would naturally be represented in a less technical institution by an advanced course in fungi. Further, the general course includes all the biology which

many students get, hence this course should be organized with particular care.

Coming then to the consideration of the general course, a study of curricula shows that there is a marked lack of unanimity among biologists as to what should be its content, and this fact causes no surprise, but is entirely reasonable in view of the diversity in needs of students. The lack of uniformity which courses exhibit arises from selection of material, for in a field so vast one can scarcely hope to treat the whole, even in a general way. If such should be attempted, we encounter at least two dangers: first, a topic must be treated so briefly that students fail to comprehend it. Any one who has tried to make Mendel's law clear to a freshman class will appreciate this statement. Second, when the student begins more advanced courses he loses the advantage of entering distinctly novel fields—we have already sucked the juice out of the orange, so to speak. But if the whole subject may not be covered, it becomes necessary to select, and continued selection through a period of time has resulted in the survival of the fittest, that is, the assembling of a number of topics which may be regarded as fundamental. These topics in a well-ordered course represent principles, for the plants or animals studied are not introduced for their own sake, but in order to illustrate one or more principles which it is desired to teach. Thus a liverwort may not be of great importance on its own account, but it illustrates alternation of generations and the probable origin of a land flora, and hence properly finds a place in a general course.

When a new field of discovery supplies facts which make a claim for introduction into the general course, they must justify the claim, lest we crowd out the tried and proved to make room for the new. The significance and value of a new fact may

be tested thus: how does it react on the already ascertained body of facts? Does it essentially modify what we have come to regard as fundamental concepts? The answer to these questions will go far in determining whether a new fact or theory shall find a place in a general course. Judged by this criterion, paleobotany has won for itself a place in any course where the relationships between plants constitutes one of the fundamental principles. Not that paleobotany needs to be introduced formally under that designation, but fossil plants may now be dealt with in an evolutionary scheme in the same way as existing ones, and our view of the plant kingdom as a whole is correspondingly broadened. To quote D. H. Scott: "Our whole conception of two at least of the great divisions of the Vegetable Kingdom—the Pteridophyta and the Gymnosperms—and of their mutual relations, is already profoundly influenced by the study of the ancient forms." In a similar way recent progress in plant anatomy has so far established a new point of view that its results must be incorporated in all but the most elementary presentation of the subject of morphology.

But there are other ways in which a new topic may justify its claim for insertion in a general course. The new facts may have such intrinsic and fundamental importance that they may fitly find place in a course, although not reacting to any considerable extent on the older material. In this way the leading facts concerning inheritance may justify the place they hold in some general courses. A real difficulty in including this topic arises from the fact that freshmen lack the antecedent training in cytology and embryology which is desirable before one can really grasp the principles of heredity.

A principle which must not be lost sight of in deciding for or against a new topic is

its pedagogic value. New subjects suffer in this respect from their lack of organization; they consist largely of a number of interesting and significant observations, but these are at first unrelated, and therefore of inferior value for teaching purposes. A good example is seen in the mass of facts which is accumulating as the result of the activity of workers along Mendelian lines. It has also been noticed that speculation has run far in advance of these facts—an observation which carries its own moral. Plant ecology is another branch of the subject which lacks organization. As Cowles has said, until recently ecology had no fundamental concepts. Moreover some of the workers who have rushed into this field have not hesitated to provide a plausible explanation for every phenomenon, with the result that careful work has been discredited along with the hasty. We should beware of the attitude of mind which leads us to explain everything. We have abundant reason to consider this matter of pedagogic value, for we must realize that sciences and especially the biological sciences are still on trial as subjects suitable for schools and colleges, and that some disappointment has been manifested at the results following their introduction. All sciences still suffer from a lack of the definite organization which has long been possessed by the classics and mathematics. Biology is indulgently tolerated by the followers of the more exact sciences; in the words of one of my engineering colleagues, "biology is largely an observational subject." Hence we do well to be sparing in our introduction of new and unorganized branches of our subject. We are in danger of sacrificing a training in exact thinking, such as is provided by comparative morphology, and gaining only intellectual haziness. That this is a prevalent and serious defect in American education is

borne out by the report of Oxford tutors concerning Rhodes scholars; the tutors readily admit the mental alertness of the American scholars, but uniformly remark upon their inability to settle down to do a long spell of thorough work.

Again, since we very properly lay more stress on nature than on books, the availability of a new topic for laboratory purposes must be considered. It is a matter of common experience that morphological work presents fewer difficulties than any other when unwieldy classes have to be marshalled section after section in overcrowded laboratories. Unless numerous assistants and abundant laboratory and greenhouse space are available, work along physiological, ecological or genetic lines is apt to result in much waste of time and few profitable results, while at the same time the student is missing the opportunity of laying a stable morphological foundation for his later studies.

Even when the best word has been said in behalf of the newer fields, the preeminence of morphology as the *sine qua non* of instruction remains untouched. Though the educational pendulum may swing far to the right and left, it returns to its stable position, and that position points to morphology. One of the dangers which a student encounters is that of specializing too early, before he has laid a solid foundation. Hence our general course must show a preponderance of that branch which experience has shown to be fundamental. Examples of the fatal consequences of an absence of adequate knowledge of morphology are not hard to find. On the botanical side we need only recall the blunders of the earlier paleobotanists, who framed phylogenies based on external structures only, and in our own day we have the sorry spectacle of experimental morphologists who have a slender grasp of morphology, and of plant

physiologists who propose theories which are at once seen to be untenable when viewed in the light of the elementary facts of histology. Work in genetics or in plant pathology carried on by those who are not rooted and grounded in morphology is bound to be of the empiric type, too greatly resembling the product of the short courses in agriculture.

What then shall be the nature of the well-ordered general course? Since a paper such as this is more or less the writer's confession of faith, I may as well conclude by telling what we are attempting to do in the institution which I represent. First, the course is one in general *biology*, in which the professors of botany and zoology lecture in turn, each completing a topic before giving place to the other. During the greater part of the year the morphology of the two kingdoms is developed, but each form selected for study is considered not on its own account, but is introduced in order to illustrate some fundamental principle. Form and function go hand in hand, each supplementing the other. Thus the course is strung on an evolutionary and also a physiological thread. Any form which does not fit in with this scheme is ruthlessly weeded out. At suitable times general topics such as evolution, heredity and certain ecological themes are formally treated. Laboratory work for the most part follows the order of topics adopted in the classroom, but while human physiology is being considered in the class-room the class is dissecting the frog in the laboratory.

Realizing that it is somewhat presumptuous for one man to speak for all botanists, I have sought the opinion of a botanist who has had long experience in teaching, Dr. John M. Coulter, and have been pleased to find that his view of the subject matter of an elementary course pretty closely cor-

responds with the one expressed in the foregoing. I take the liberty of quoting:

I should say that the elementary course or courses in botany should always be synthetic. Fundamental in the synthetic presentation of botany I should say is morphology, for I do not believe that any effective work can be done without some knowledge of the structures involved. Then I should say that the morphological thread that runs through the course should string together the most important physiological phenomena as explanations of morphological structure. In fact, I would not regard any morphology as significant that could not be explained in terms of physiology; and on the contrary, I would not regard any physiology as worth while that could not be fitted into morphological structure. In other words, I can not divorce the machine from its work. Naturally in this statement ecology becomes merely a form of physiology. This would be my general notion as to the content of an elementary course in botany.

What should be given afterwards depends entirely upon the size of the botanical staff and its differentiation in interest. After the synthetic course, I think there should be opportunity to develop morphology, physiology, ecology, etc., independently. Of course, experimental morphology should come in as a hybrid between morphology and physiology. I should say that genetics would come after almost everything else.

M. A. CHRYSLER

UNIVERSITY OF MAINE,
ORONO, ME.

EXPERIMENTALISM IN ZOOLOGY

THE followers of science have shown at all times a marked disposition to readjust the style of their intellectual apparel to new conditions, and in this respect the zoologist is no exception. There are some among us who still prefer to appear in the ancient and respectable mental garb of the systematist, others who adorn themselves in the Empire costume of the comparative anatomist, and still others who have put on the Victorian attire of the embryologist. But he who wishes to be truly modern is content to clothe himself in only the scanty raiment of the experimentalist. A glance

at this last class shows it to be made up of the young and the would-be-young. This latest style, unlike its predecessors, is not a creation from Paris or from London, but is largely a home-product, the result of what its inceptors would call internal factors, those conveniently vague things about which we know so little. Although we are not wholly clear as to the process by which we have come to be experimentalists, we are convinced that it depended upon something like an irreversible reaction and that we have come to stay.

The experiment, however, is by no means a modern invention. As early as the thirteenth century Roger Bacon was proclaiming to unsympathetic scholars its soundness as an instrument for the discovery of truth. In his *opus majus* he maintains that

There are two modes of knowing; by argument and by experiment. Argument concludes a question; but it does not make us feel certain, or acquiesce in the contemplation of truth, except the truth be also found to be so by experience.

And still farther on in the same work he declares that

Experimental science, the sole mistress of speculative sciences, has three great prerogatives among other parts of knowledge: First, she tests by experiment the noblest conclusions of all other sciences; next, she discovers respecting the notions which other sciences deal with, magnificent truths to which these sciences themselves can by no means attain; her third dignity is, that she by her own power and without respect of other sciences, investigates the secrets of nature.

Although Roger Bacon's utterances in favor of experimental science were made over three centuries before the days of his illustrious fellow countryman, Francis Bacon, and at a time when such utterances were dangerous, they were by no means the earliest expression of the experiment. Some sixteen centuries before Roger Bacon's time, Aristotle wrote in simple language an account of what is probably the

earliest recorded biological experiment. It deals with the physiology of the senses and reads as follows:

By crossing the fingers a single object under them appears to be two and yet we do not say there are two; for sight is more decisive than touch. If, however, touch were our only sense, our judgment would declare that the single object is two.

Thus Aristotle employed the experimental method for the discovery of truth. With all this history behind us it may seem strange that we have been so slow in appreciating the significance of this method. But it must be remembered that the biological sciences, unlike physics and chemistry, have had an enormous volume of descriptive material to handle, and that it was only after this task was well under way that really fundamental problems could be attacked. It is also to be kept in mind that such sciences as chemistry and physics have begun to yield only recently results and methods which have been of direct service to biology. Viewed from this standpoint the whole course of development of the methods employed in biological research is a natural one, and, though we may not fully appreciate all the steps by which we have reached this new road to discovery, we are persuaded that the course we have taken is the result of the untrammelled growth of our science.

With the acceptance of the experimental method as a part of the means of biological research comes the responsibility of training students in the new way of work. To those of us whose zoological apprenticeship centered round the paraffin bath and the microtome, this is no simple proposition. With little physics, less chemistry, and almost no mathematics we find ourselves poorly equipped to meet the new emergencies. One of my colleagues trained in this fashion seems never to appreciate the fact that there is a third dimension in space, and

in my case mathematics is metamorphosed from one of the most exact forms of expression into one of the most inexact. Although we may take consolation in the fact that even so illustrious a physicist as Faraday was essentially unmathematical, we can not look upon the deficiencies that I have just pointed out without recognizing that they are real shortcomings. These defects in our early training can not be ascribed to lack of reasonable foresight on the part of our teachers or even to our own idleness. They are the natural result of the prodigious rate at which our science has been growing, a rate that made it impossible for even the best informed of a generation ago to predict the needs of today. This is true not only of the present, but also of the past. Darwin's early training was that of a physician, and Huxley actually went into medical practise. Both men in their early days never entered a biological laboratory, for the obvious reason that no such institution existed, and both regretted their educational deficiencies.

Inadequately trained ourselves, how are we to meet the problem of training others in the new directions? The situation seems to include to a certain degree the impossibility of lifting oneself by one's bootstraps. But I suggest that while tugging at the straps a slight jump will lift us a little, and the jump that seems to me to be advisable is to recommend that our students pay more attention to chemistry and physics, sciences in which the experimental method is well developed and which are yielding results that are applicable more and more to the fundamental problems of biology. Such a training, when rigorously pursued by a student with a clear understanding of its relations to biological work, is bound to be richly productive as soon as it is turned in the appropriate direction.

But physics and chemistry are, in my

opinion, only part of the preliminary scientific training for these new lines of work. The zoologist is continually confronted at least in his study of the higher animals with those complicated conditions that we recognize in our own mental states. That such conditions exist in varying degrees in the lower animals no one can deny. The questions that arise concerning them are what is their nature and to what extent are they present in the lower forms. These problems are psychological, and I should, therefore, regret to see a prospective zoologist omit from his preliminary training a reasonable grounding in this field of investigation. In one way, however, I regard psychology as less important for the beginner than physics and chemistry. In it the experimental method is less completely developed than in the two sciences just named. In truth, it is in this respect much like biology itself and in need of help especially from the side of chemistry. The genius of Helmholtz seems to have had such an overwhelming influence on most psychologists that they have been content to study almost exclusively the physics of sensory phenomena to the neglect of other psychological fields, such as the chemistry of the central nervous states. But though psychology may have its own difficulties, I nevertheless regard it as a field that should be included in the general training of every student who aspires to a broad-minded and productive scholarship in zoology. With the botanist it may be different. He sometimes counts himself fortunate to have escaped the problem of mind, but to my way of thinking this very problem is one of those elements which makes zoology so intensely interesting.

But the young zoologist trained in the experimental method by physics and chemistry, and heedful of the fact that the material of his investigation may exhibit

among its characteristics some of the phenomena of intelligence, must still assume a very different attitude toward his work from that which most of us were accustomed to in the laboratories of twenty or thirty years ago. Those were the days of morphology, when the visible structure of the organism was all important and the problem of the homology of various parts, the integrity of the germ layers, and so forth were of foremost interest. The attitude of the average student of those days was essentially anatomical, and the anatomical conception of an organism was that of a standing motionless object. Immensely important as this view was, it lacked the really essential characteristic of the living thing, its incessant activity. The new view, on the other hand, includes just this feature. The student of thirty years ago was concerned with methods of preserving animals and he never felt safe until his catch was in the alcohol jar; the modern student is all alert to keep his stock alive and he consigns it to preservatives with funereal rites. This change in attitude is part and parcel of the new growth and is working a slow but steady revolution in the equipment of our laboratories.

With all this overturning and revolution going on in our advanced work, what can we say of our elementary instruction. Here we are supposed to keep to those aspects of the subject that are well established and that are not open to fundamental revision. Moreover, in this direction the procedure of lecture work and laboratory routine is well established in text-books and the like, and the instructor, in keeping in these well-worn paths, is on what seems to him to be safer grounds. But even the elementary courses, in my opinion, must not be devoid of promising outlook. They should include a reasonable amount of the new work. But to accomplish this without printed

guide or previous training is not an easy task for the older teacher. Here is perhaps the point in the new work at which the young and the would-be-young are most clearly differentiated. To me the contemplation of this subject is embarrassing and I pass it by. But for the encouragement of those who are in my plight, I must add a word from my own experience.

I believe that some of us who are older teachers fail to appreciate, from our disinclination to give the matter a trial, how easy it is to arrange elementary courses, especially the laboratory exercises in such courses so as to illustrate animal activities by the experimental method. I know that in my own experience a laboratory course which I gave to high-school teachers a year or so ago was in this respect immensely illuminating. I had no idea that the new methods could be applied so directly. To give some notion of the nature of the work that can be carried on in such courses let me name some of the exercises that we found serviceable: the effects of light on the movements of planarians, earthworms, mealworms and the larvæ and adults of flesh-flies; the combined influences of gravity and light on the movements of fruit-flies; the effects of odorous substances on the movements of earthworms and on the gathering of fruit-flies; the feeding reactions of planarians, catfishes and toads; the means of locomotion in earthworms, mealworms and snails; the reactions to stimulation in *paramæcium*, and its rate of reproduction; regeneration in planarians and earthworms; heredity in fruit-flies. These and other like exercises were found surprisingly applicable to elementary work and have encouraged me to believe that practise in experimental work may well be introduced into elementary courses.

Such work, moreover, is not without its beneficial influence on the teacher. No two

animals are ever alike in their reactions, and in this respect they differ vastly more than they do in their structure. Although each exercise can be made to lead to a general conclusion for all students concerned, the details of the work soon come to be individual. The instructor is called upon, therefore, rather as an adviser in method than an authority in facts, and from this standpoint his attitude toward his work is much more natural than what it often is in purely anatomical exercises. Woe be to him if he begins to tell what a given animal at a given moment will do! I know of no elementary biological exercises that are better adapted than these to develop independence and originality in the student and to reduce the instructor to his true position, that of a student of greater maturity than those about him. As a result of this experience, I look with great hope on the steady introduction of experimental exercises into our elementary work. Certainly the conception of an animal that is gained from work such as this is much nearer the truth than that which we have been instilling through alcoholic specimens.

But if these are the realities of the experimental method, what are its vanities? I think the chief pitfall that besets the experimentalist is apparatus. What a strange allurements this feature of the situation has for us! What can be more pleasant to the eye than beautiful apparatus in glass cases or a grand array of delicate contrivances built up upon a table! And they are always so interesting to the visitor! But I shall never forget the comment of a friend of mine who on looking over an extensive device of my own construction finally remarked that the justification of such work as biological did require a goodly supply of brass. But if apparatus is our pitfall, we must remember that many of the pioneers in the new movement have

already demonstrated to us fundamental results by means as strikingly simple. To Loeb the problem of the universe is soluble in a finger-bowl; to Morgan in a milk-jar; and we must never forget that the importance of a result is often inversely proportional to the complication of the apparatus by which it was attained. With these examples before us, let us avoid the pitfall of bright glass and shining metal.

I have entitled this paper "Experimentalism in Zoology" and I have nowhere used the term experimental zoology. This has been intentional, for I do not believe in this term. The new movement does not mean a new province in zoology; it is a new method of attacking old problems. It will, of course, lead us to new fields, but it is method rather than matter. We are not exchanging old lamps for new but burning the old lamp in a new way. I therefore resist the term experimental zoology. We are all still zoologists and we have simply added to our equipment the experimental method. As each one, old or young, realizes the significance of this method and the great power that it puts in his hand, he will adopt it in proportion to his needs and abilities. In this way it is gradually pervading the whole fabric of biology from the realm of the systematist to that of the ultra-modernist. Our times are full of such changes. To-day we men vote, to-morrow our women will vote. Let all such changes come as natural growths.

G. H. PARKER

HARVARD UNIVERSITY

*THE PRODUCTION OF RADIUM, URANIUM
AND VANADIUM ORES IN 1913*

PROBABLY no other mineral is mined which has so large a hold on public attention and at the same time has so small a total monetary value as the uranium minerals. This interest is, of course, due not to the minerals as such,

nor to the uranium they contain, but to the accompanying radium, which is found only with uranium. Hitherto the interest in radium, though lively, has been largely academic, on account of the marvelous qualities which it displays when compared with better-known elements. Toward the end of 1913, however, public interest became almost feverish, owing to the apparent cures of cancer wrought by the application of the gamma rays given off by radium.

Uranium minerals were produced in commercial quantity in the United States in 1913, as shown by preliminary statistics gathered by Frank L. Hess, of the United States Geological Survey, only in Colorado and Utah, and although during the year some pitchblende was mined in Colorado in the Belcher & Calhoun mines, only a few pounds were sold, though 50 dry tons of low-grade material carrying 1.49 per cent. uranium oxide (U_3O_8) was shipped to France from the Kirk mine. This had been mined a previous year. Carnotite, a yellow powdery or waxy mineral found in the sandstones of the high plateau between the Rocky Mountains of Colorado and the San Rafael Swell of Utah, south of the Book Cliffs, furnished the whole production.

Carnotite, as the word is ordinarily used, is a potash or lime uranium vanadate. Several vanadium minerals occur with the carnotite, so that in mining for uranium a great deal of vanadium is also obtained. At Newmire, San Miguel county, Colo., one of the vanadium minerals, roscelite, occurs practically free from uranium and is worked for vanadium alone.

The total mine shipments of uranium and vanadium, as shown by preliminary figures, were equal to 2,140 tons of dry ore, carrying an equivalent of 38 tons of uranium oxide. The vanadium in carnotite ores shipped, together with that which is estimated to have been produced from the Newmire district, was equivalent to 914 tons of vanadium oxide. These quantities are equal to about 32.3 tons of metallic uranium and 412 tons of metallic vanadium.

The Bureau of Mines has determined that carnotite carries about 90 per cent. or even a little more of the theoretical quantity of radium in equilibrium with uranium, which, according to Rutherford ("Radioactive substances and their radiations," p. 16), is equal to about 1 gram in 3,000 kilograms of uranium. Assuming that 90 per cent. of the radium is recoverable, this would give 16.40 grams of hydrous radium bromide, worth, about \$120 a milligram of metallic radium, about \$1,055,000. The total value of the carnotite ores sold was about \$142,000, which represents the uranium value only, as little was paid for the vanadium content and the figures for these receipts are not yet in hand.

The production of the year was the largest ever made, according to the Geological Survey figures, that for 1912 being equivalent to 26 short tons of uranium oxide (22 tons of the metal), and that for 1911 being equivalent to 25 tons of uranium oxide (21.2 tons of the metal)—an increase of nearly 50 per cent. for 1913.

Of the quantity produced, apparently 19.25 tons of uranium oxide, containing the equivalent of 8.3 grams of hydrous radium bromide, was shipped to Europe, and 18.75 tons, containing the equivalent of 8.1 grams of hydrous radium bromide, was retained in this country, although in tonnage the quantity retained in this country, 1,193 tons, was larger than that shipped to Europe, which was apparently 942 tons. One of the principal producers for foreign trade did little work for more than half a year, owing, it is reported, to the fact that its factory in Liverpool had not been completed. Had the factory come into operation sooner the exports would have been considerably larger.

A prominent feature of uranium and vanadium production during the year was the change in method of payment by American buyers, who no longer paid for the vanadium content in the ore but bought it on the basis of the uranium oxide content alone, though they received payment for the vanadium

abroad. However, the miner received more or less compensation in a higher price for the uranium oxide he sold. Prices varied greatly and returns to the Survey show that the price per pound for contained uranium oxide ranged from \$1 for ores carrying 0.6 per cent. uranium oxide to \$4.60 for one lot carrying 3.15 per cent. uranium oxide and 4.82 per cent. vanadium oxide.

The demand for carnotite at increasing prices caused a large amount of prospecting, and the carnotite-bearing area was shown to extend from the Paradox country westward into the Dry Valley region of Utah, lying between Monticello and the La Sal Mountains. Farther west and south deposits of carnotite were found on Crescent and Trachyte creeks, in the Henry Mountains, and also southwest of the mountains.

During the fall a geologic reconnaissance of the uranium and vanadium deposits of Utah was made by Frank L. Hess and B. S. Butler, of the United States Geological Survey. They covered the territory lying between the Wyoming line and the south side of the Henry Mountains, and east of the San Rafael Swell. The deposits, as shown by the outcrops, are nearly all in small pockets, part of which are comparatively rich. All the newly found localities are far from railroad and the hope for commercial production from them lies in concentration on the ground by some cheap process, and many experiments are being carried on to develop such a process. Toward the end of the year steps were taken for the erection of a concentration plant in Dry Valley, 15 miles north of Monticello. A plant was put up on Mesa Creek, Colo., and another was said to be in course of erection in the Gateway district. A preliminary report on the uranium and vanadium deposits of Utah will probably be issued during the spring.

The Standard Chemical Company actively produced radium at its plant at Canonsburg, Pa., and the Radium Company of America established a plant and did preliminary work at Sellersville, Pa.

THE PREMEDICAL CONFERENCE

THE Cincinnati Conference of Academic Institutions and Medical Colleges on Premedical Education was held at the University of Cincinnati, January 16-17. The occasion marked the installation of Dr. Christian R. Holmes as dean of the Medical College. The inauguration address was given by Dr. Wm. H. Welch, of Baltimore, his subject being "The Development of Medical Education in America." Dr. Welch was later entertained at a banquet.

Representatives of many of the medical and academic institutions of the Middle West conferred on the requirements of premedical education with a view to bettering and standardizing the preparatory work. Among those who addressed the conference were Pres. Charles W. Dabney, Drs. Wm. H. Welch, Charles Dean Bevan, John A. Witherspoon, N. P. Colwell, Henry B. Ward, Michael F. Guyer, Lauder W. Jones, Brown Ayres, Edgar Brandon, Dean Christian R. Holmes, Paul G. Woolley, Harry Marshall and others. There were present the secretary, two ex-presidents and the president of the American Medical Association.

A committee consisting of Professors Michael F. Guyer (chairman), Harry N. Holmes, Lauder W. Jones, Henry McE. Knowler and E. L. Rice drew up the following resolutions, which the conference adopted:

In view of the ideas expressed in this conference, be it

Resolved, That the representatives of the various colleges confer with their respective faculties to ascertain:

1. What courses of a premedical nature are offered by them in chemistry, physics, biology and languages.
2. What changes, if necessary, can be made to establish uniformity of essentials in premedical training.
3. Whether it is possible to reduce the total time now required to obtain the M.D. degree by eliminating duplication of work existing in graded schools, high schools, colleges and medical schools. Your committee is of the opinion that this is feasible.
4. What arrangements are made for granting the bachelor's degree after satisfactory completion of two or three years' college work and one or two years in a Class A plus medical school.

Be it further resolved, That the action taken by the various faculties be reported to Paul G. Woolley, University of Cincinnati, chairman of the general conference committee, and that this committee may, at its discretion, call another general conference of the colleges interested in this movement.

It was generally agreed that physics, biology, chemistry and modern languages have an unquestioned place in the premedical education. Reprints containing the discussion and addresses can be obtained on request from the university.

The delegates inspected the medical college laboratories and the new \$4,000,000 city hospital, which Dr. Holmes is just bringing to completion. The plans for the new medical college building, on the hospital site, were exhibited.

THE AMERICAN CHEMICAL SOCIETY

THE forty-ninth meeting of the American Chemical Society will be held in Cincinnati, Ohio, from Tuesday, April 7 to Friday, April 10, inclusive. A meeting of the council will be held at the Hotel Sinton on Monday evening, April 6. The Hotel Sinton has been chosen as headquarters.

The general meetings and the meetings of divisions will be held at the University of Cincinnati.

The transportation committee has arranged a number of interesting visits to local industrial plants. It is a well-known fact that Cincinnati has a very large variety of industries which are strictly chemical or very closely allied. This committee has already arranged trips to the Filtration Plant, Proctor & Gamble's, the home of Crisco and Ivory Soap; Globe Soap Co., Diamalt Co., Andrew Steel Works, Boldt Glass Co., the New Cincinnati Hospital, the largest and most modern city hospital in the world; Machine Tool Plants, Rookwood Pottery, Lloyd Brothers, W. S. Merrill Chemical Co., and many others.

In addition to these inspection trips the committee is planning to devote Friday, April 10, to visit adjacent industrial plants—an all day excursion. It is the plan during the morning

to go to Middletown and inspect the plant of the American Rolling Mills, the home of Ingot Iron. After visiting this plant the party goes to Dayton, where members of the Cincinnati Section, residents of Dayton, have arranged an inspection trip through the plant of the National Cash Register Co. Negotiations are now in progress to have Mr. Wright give an exhibition of his latest aeroplane, including the stabilizer.

The following provisional program will give an idea of the plans for the Cincinnati Meeting:

Monday, April 6, evening, council meeting.

Tuesday, April 7, morning, general meeting; afternoon, excursions; evening, smoker at zoo.

Wednesday, April 8, morning, division meetings; afternoon, excursions; evening, concert by the Cincinnati Symphony Orchestra at Emery Hall.

Thursday, April 9, morning, division meetings; afternoon, division meetings; evening, subscription dinner.

Friday, April 10, excursion to American Rolling Mills, Middletown, O., and the National Cash Register Company, Dayton, O.

Following are the addresses of the Divisional and Sectional Secretaries:

Divisions:

Agricultural and Food Chemistry: G. F. Mason, H. J. Heinz Company, Pittsburgh, Pa.

Biological Chemistry: I. K. Phelps, Bureau of Chemistry, Washington, D. C.

Fertilizer Chemistry: B. F. Carpenter, Virginia Carolina Chemical Co., Richmond, Va.

Industrial Chemists and Chemical Engineers: S. H. Salisbury, Jr., Lehigh University, South Bethlehem, Pa.

Organic Chemistry: C. G. Derick, Morris Ave., Lincoln Place, Urbana, Ill.

Pharmaceutical Chemistry: A. P. Sy, University of Buffalo, 24 High St., Buffalo, N. Y.

Physical and Inorganic Chemistry: R. C. Wells, U. S. Geological Survey, Washington, D. C.

Sections:

India Rubber Chemistry: Dorris Whipple, the Safety Insulated Wire and Cable Co., Bayonne, N. J.

Water, Sewage and Sanitation: Harry P. Corson, State Water Survey, Urbana, Illinois.

All Divisions of the Society will meet. The Water, Sewage and Sanitation Section has

announced that it is planning a special conference on Standard Methods of Water Analysis. The Rubber Section hopes to have a large meeting, as Cincinnati is conveniently located to some of our largest rubber manufacturing centers.

SCIENTIFIC NOTES AND NEWS

The following fifteen candidates have been selected by the council of the Royal Society to be recommended for election into the society: Dr. Edgar Johnston Allen, Mr. Richard Assheton, Mr. Geoffrey Thomas Bennett, Professor Rowland Harry Biffen, Dr. Arthur Edwin Boycott, Mr. Clive Cuthbertson, Dr. Henry Hallett Dale, Mr. Arthur Stanley Edgington, Professor Edmund Johnston Garwood, Mr. Thomas Henry Havelock, Dr. Thomas Martin Lowry, Professor Diarmid Noël Paton, Mr. Siegfried Ruhemann, Dr. Samuel Walter Johnson Smith and Dr. Thomas Edward Stanton.

The seventieth birthday of Professor A. Engler, the distinguished Berlin botanist, will be celebrated on March 27, when a marble bust will be presented to him.

PROFESSOR R. W. WOOD, of the Johns Hopkins University, gave in London, on February 27, the first Guthrie lecture of the Physical Society, his subject being "Radiation of Gas Molecules Excited by Light."

DR. GEORGE E. DE SCHWEINITZ, professor of ophthalmology in the University of Pennsylvania, was given by the university the degree of doctor of laws, at its recent university-day celebration.

DR. E. W. HOBSON, Sadlerian professor of pure mathematics at the University of Cambridge, has been nominated to represent the university on the occasion of the celebration on June 29-30 and July 1 of the three hundredth anniversary of the foundation of the University of Groningen.

DR. A. SMITH WOODWARD has been elected president of the Geological Society of London.

OFFICERS of the Royal Astronomical Society have been elected as follows: *President*, Major E. H. Hills; *Vice-presidents*, Dr. F. W. Dyson,

Dr. J. W. L. Glaisher, Professor H. F. Newall and Professor H. H. Turner; *Treasurer*, Mr. E. B. Knobel; *Secretaries*, Professor A. S. Eddington and Professor A. Fowler; *Foreign Secretary*, Professor Arthur Schuster.

At the recent annual meeting of the State Microscopical Society of Illinois the constitution and by-laws were revised and the following officers elected for the ensuing year:

President—David L. Zook.

First Vice-president—Walter F. Herzberg.

Second Vice-president—Francis T. Harmon.

Treasurer—Frank I. Packard.

Corresponding Secretary—N. S. Amstutz.

Secretary—V. A. Latham.

Curator—Henry F. Fuller.

Trustees—M. D. Ewell, B. U. Hills, Albert McCalla, S. S. Graves and W. G. King.

An annual conversazione meeting will be held on March 12 at the rooms of the Chicago Press Club. The annual soirée in connection with the Chicago Academy of Sciences, Lincoln Park, will be held some time in April.

"MEN of the Old Stone Age in Europe: their Environment, Life and Art" was the subject of the annual Hitchcock Lectures, just given at the University of California as the series for 1914. This year's Hitchcock Lecturer was Dr. Henry Fairfield Osborn, research professor of zoology in Columbia University, and president of the American Museum of Natural History. The latest fruits of excavation and comparative study in various parts of the world were gathered together by Professor Osborn in these lectures. He told of *Pithecanthropus*, the earliest human type as yet discovered; of the recent important English discovery of the Piltdown man; of the Heidelberg man; of the Neanderthal human type; of the Crô-Magnon race, and of the local Grimaldi race. He described the mural art of such caverns as those of Font de Gaume, in France, and Pasiega, Castillo and Altamira, in Spain. After telling of the appearance of the Grenelle race and the Azilian-Tardenoisian culture, he completed his lectures with an account of the beginning of the Neolithic Period, its culture and the sources of its main races.

DR. W. M. DAVIS, Sturgis-Hooper professor

emeritus at Harvard University, has gone from Cambridge on a trip to several of the island groups in the Pacific Ocean, where he will study coral reefs. On the outward voyage he will visit the Fiji and other islands, in August he will attend the colonial meeting of the British Association to be held in Australia, and in September will take part in a supplementary meeting promoted by the government of New Zealand. On the return voyage, he will stop at the Society Islands. The trip is made possible by a grant from the Shaler Memorial Fund. Professor Davis lectured before the Colorado Scientific Society at the State School of Mines, Golden, Colo., on "The Front Range of the Rocky Mountains," February 3; at the State University, Boulder, Colo., on "Theories of Coral Reefs," February 4; at Brigham Young University, Provo, Utah, on "The Lessons of the Colorado Canyon," February 6, and before the Leconte Club at the University of California, Berkeley, Cal., on "The Topographic Features of Desert Regions," February 10.

The Cutter lectures on preventive medicine and hygiene are to be given at the Harvard Medical School this year by Charles V. Chapin, M.D., superintendent of health, Providence, and Dr. Cressy L. Wilbur, chief statistician, Bureau of the Census. Dr. Chapin will give six lectures on municipal sanitation, as follows:

March 20, "Science and Sanitation."

March 27, "Efficiency of Public Health Measures."

April 2, "Organization of the Health Department."

April 9, "Research and Publicity."

April 16, "Nuisance Problems."

April 30, "Contagious Disease Problems."

Dr. Wilbur's subject will be "Vital Statistics in Massachusetts and the United States," and the dates are March 25 and 26.

DR. JOHN M. CLARKE, state geologist of New York, lectured before the Society of Sigma Xi of the Ohio State University on December 27, his subject being "Land Bridges Across the Atlantic."

PROFESSOR ARTHUR H. BLANCHARD, of Columbia University, on February 24, delivered illustrated lectures at the University of Tennessee on the subjects: "Bituminous Macadam and Bituminous Concrete Pavements" and "Highway Engineering in Europe" and an illustrated lecture on "City Pavements," before the chamber of commerce of the city of Knoxville.

PROFESSOR J. ANSEL BROOKS, of Brown University, on March 2, delivered an illustrated lecture on "The Principles of Efficiency Engineering applied to Highway Engineering," before the graduate students in highway engineering at Columbia University.

ON February 28 Sir J. J. Thomson began a course of six lectures at the Royal Institution on recent discoveries in physical science.

PORTRAITS of Dr. John Herr Musser, late professor of medicine in the University of Pennsylvania, and of Dr. Rush Shippen Huidekoper, first dean of the school of veterinary medicine, were presented to the University of Pennsylvania at its university-day celebration on February 23.

MR. AND MRS. PAUL J. SACHS have established a fund for the American Museum of Natural History to be known officially as the Angelo Heilprin Exploring Fund. The money is given in memory of Angelo Heilprin and is to be applied each year to any exploring purpose the museum authorities deem fitting.

MEMORIAL services for Alfred G. Compton, late professor of physics at the College of the City of New York, were held on March 9 in the great hall of the college. Professor Compton entered the college at its foundation and was graduated with the class of 1853. Since his graduation until his retirement in 1911 he was a member of the faculty. Among those who made addresses were: Professor Michael I. Pupin, of Columbia University; Professor Adolph Werner, of the college, and Dr. John H. Finley, state commissioner of education and formerly president of the college.

PROFESSOR EDWIN J. HOUSTON, formerly of the Central High School of Philadelphia and the Franklin Institute, well known for his

work in electrical engineering and for his writings on this and other departments of physics, died on March 1, aged seventy years.

COLONEL ALEXANDER ROSS CLARKE, the distinguished British geodesist, died on February 11, at the age of eighty-five years.

DR. JULIA COCK, consulting surgeon to the New Hospital for Women and dean of the London School of Medicine for Women, died on February 7, aged fifty-four years.

THE U. S. Civil Service Commission announces an examination for junior pharmacologist, on April 8, to fill vacancies in this position in the bureau of chemistry, Department of Agriculture, Washington, D. C., at salaries ranging from \$1,200 to \$1,500 a year.

JOHN DEWRANCE has presented £2,000 to the donation fund of the Royal Society. The income arising from this fund is applied in promoting experimental researches.

THE Bermuda Biological Station for Research will be opened in June for a period of about six weeks. Members have facilities for shore collecting, dredging and marine towing down to a depth of 100 fathoms. Inquiries should be sent to Dr. E. L. Mark, 109 Irving St., Cambridge, Mass.

ACCORDING to the resolutions of the meeting of October 25, 1912, at Lyons, the secretary's office of the permanent committee for the International Veterinary Congresses has been definitely established at The Hague from January 1, 1914, under the patronage of the Dutch Department of Agriculture, Industry and Commerce. The address of the office is as follows: "Secretary's Office for the Permanent Committee for the International Veterinary Congresses at The Hague, Stationsweg 74 (Int. Tel. 848)." Correspondence, publications, etc., as far as they are not sent to the president of the committee, Dr. A. Lydtin, at Baden-Baden, or to the secretary, Professor Dr. D. A. de Jong, at Leyden, are to be addressed to this office.

WITH the cooperation of fifty different organizations devoted to social progress and civic welfare, Reed College will hold a conference on May 15, 16 and 17, as a clearing house for

welfare workers and a stimulation for the activities of the city for the year 1915. This Portland 1915 conference will be similar in scope and method to the Reed College conference on the conservation of human life held last May.

A NEW edition of "Les observatoires astronomiques at les astronomes," first published in 1907, is in course of preparation, under the direction of members of the Royal Observatory of Belgium, with Professor P. Stroobant as chairman. He will be glad to receive information from directors of observatories and private astronomers concerning their work and publications.

UNIVERSITY AND EDUCATIONAL NEWS

THE College of Agriculture and the Mechanic Arts of North Carolina is preparing to celebrate on the first three days of October the twenty-fifth anniversary of the first opening of the college. A tentative program has been adopted at a meeting held in the office of Governor Locke Craig, who is *ex officio* chairman of the board of trustees and at the head of the advisory committee which is cooperating with the committee of arrangements. In order to make the quarter-centennial celebration a complete success, efforts will be made to have in connection with it reunions of the twenty-two classes which have so far been graduated. There will also be social meetings, addresses by some of the distinguished men who took part in the founding of the college, and other interesting features. The celebration proper will take place on the morning of October 3, with the principal addresses, but the other meetings will not be at all lacking in interest. Guests who will be held in special honor throughout the celebration will be those who took part in the movement which resulted in the founding of the college.

THE faculty and students of the University of Pittsburgh held a banquet on February 25.

At the end of the current college year, Dr. Albert Benedict Wolfe, head of the department of economics and sociology, will withdraw from the Oberlin faculty in order to accept the headship of the department of sociology and economics in the University of Texas.

PROFESSOR O. PERRON, of Tübingen, has accepted the professorship of mathematics at Heidelberg, as successor to Professor L. Koenigsberger.

DISCUSSION AND CORRESPONDENCE

STANDARD UNITS IN AEROLOGY

IN SCIENCE, January 2, 1914, p. 31, it is stated that Blue Hill Observatory would use the new units for atmospheric pressure and temperature, *i. e.*, the units proposed by Köppen at Monaco in 1909 and again by V. Bjerknes at the Vienna meeting of the International Commission for Scientific Aero-nautics, 1912. In this system, pressure is expressed in bars or decimal parts thereof, such as decibar, centibar and millibar. One million C.G.S. units constitutes a bar.

Professor A. E. Kennelly, visiting this observatory, called attention to the inconsistency of such use of the term "bar." Unknown to meteorologists at home or abroad, apparently, the bar has been defined and used with a different value. Professor T. W. Richards in 1903,¹ suggested that the pressure of a dyne per square centimeter be called a bar;² and while investigation shows that somewhat similar suggestions had been made by others, Richards's was independently made, original and legitimately deduced. Kennelly³ and others following Richards have used the bar in this sense. It has therefore priority of definition and usage and is moreover the logical and appropriate unit of pressure. For the unit proposed by the aerologists, a more fitting designation would have been "aer" or "atmos."

Unless some protest be made against the proposed bar of the aerologists, we add to the confusion of units and terms already existing in meteorology. It is important too that we

¹ Publication 7, Carnegie Inst., 1903, p. 43.

² "New Method of Determining Compressibility," T. W. Richards and W. N. Stull, *Jour. Am. Chem. Soc.*, Vol. XXVI, April, 1904.

³ "Convection of Heat from Small Copper Wires," A. E. Kennelly, C. A. Wright and J. S. Van Bylevelt, *Trans. Am. Inst. Elec. Engineers*, June, 1909.

make the correction *now* at a time when we are trying to break away from the old order, attempting to introduce rational units in place of the old arbitrary ones. It is somewhat embarrassing for one who has advocated the introduction of absolute units to acknowledge the validity of the criticism of chemist, physicist and engineer; but fortunately the corrections can be made readily by changing the millibar of the aerologist to kilobar. In the conversion tables which are in course of preparation, this will be done.

Briefly, the term "barad" was proposed by a committee of the British Association for the Advancement of Science, 1888, as a suitable term for the unit of pressure, one dyne per square centimeter. Some years later Ostwald advocated the use of one million of these units as the standard, but gave the standard no name. The term *bar* was proposed by Richards in 1903 for the small unit of pressure, one dyne per square centimeter; and *megabar* for a C.G.S. atmosphere. So far as I can ascertain this is the first case in which a clear-cut definition of an absolute atmosphere has been used in actual investigation. He has consistently used this unit megabar as the basis of his work ever since. Richards's atmosphere is 0.987 of the ordinary sea-level atmosphere or 1.020 kilograms per square centimeter; and under the new order agrees with the standard level of Köppen, the million-dyne level at about 106 meters elevation.

It seems almost unnecessary to argue that the smaller bar should be the basic unit and not some multiple. And again it is doubtful if bar is the best designation for the pressure of an absolute atmosphere. Megabar is not altogether inappropriate and has priority of usage especially in the literature of chemistry. A megabar in the aerologist's notation would be the pressure of a million atmospheres, a magnitude not often dealt with. On the other hand, we often need to refer to pressures smaller than the millibar of the aerologist. The bar of the chemist and physicist is conveniently divisible down to its millibar, *i. e.*, a thousandth of a dyne per square centimeter.

The following table contrasts the two sys-

tems. At Dr. Richards's suggestion it is restricted to those terms most likely to be used.

Chemist's and Physicist's (to Former Aerolo- gist's (to be Used Hereafter) Abandoned)		Remarks
.....	1 megabar	One million atmospheres, far beyond our present possibilities of direct measurement.
1 megabar	1 bar	The absolute atmosphere; equal to 750.1 mm. mercury or .987 usual sea-level atmosphere. One megadyne per square centimeter acting through one cubic centimeter does one megerg of work.
1 kilobar	1 millibar	One kilodyne per square centimeter.
1 bar?	One dyne per square centimeter acting through one cubic centimeter does one erg of work.

There would be no objection to giving the term megabar or absolute atmosphere some convenient nickname such as "aer" if megabar is too ponderous. It has been suggested by Professor Richards that for historical reasons the pressure of 10,000,000 dynes (ten absolute atmospheres) might be named after some pioneer in meteorology, as Guericke or Torricelli, after the analogy of the "watt," "joule," "ampere," etc., but this need not be insisted on at present.

ALEXANDER McADIE

BLUE HILL OBSERVATORY,
February 28, 1914

ACADEMIC ELECTIONS

TO THE EDITOR OF SCIENCE: In connection with the table of percentages accompanying my article on "Academic Student Elections," in SCIENCE for January 16, a correspondent has called my attention to some inaccuracies in copying percentages from Professor Ferry's tables, on which the article was based. With one exception they do not seem very important. This exception is in connection with the work in biology at Bowdoin College. The entry was from the wrong column of Professor Ferry's extended table, and to Bowdoin was assigned the lowest record in this subject. A

considerably lower record, more than a third lower, belonged to another institution.

It seems only fair to Bowdoin College, and especially to its professor of biology, to publish this correction of an unfortunate oversight.

W. LeCONTE STEVENS

LEXINGTON, VA.,

January 31, 1914

SCIENTIFIC BOOKS

Chippewa Music. II. By FRANCES DENSMORE. Smithsonian Institution. Bureau of American Ethnology. Bulletin 53. 1913. Pp. 314. 51 illustrations. 180 songs. 14 tables giving "melodic analysis of 340 songs." 7 tables of "rhythmic analysis" and a table giving "comparison of metric unit of voice and drum."

Bulletin 53 together with bulletin 47 (1910) are devoted to Miss Densmore's study of Chippewa music begun in 1907 and brought to a close in the present volume. In this bulletin the author presents the results of six years of labor, gathering songs from the Chippewa in their native environment and making careful studies of the songs themselves. By these means she has sought to answer three questions: What do the Chippewas sing? How do they sing? Why do they sing? The answers to the first two are presented in a clear, painstaking manner and in such form as to make them conveniently serviceable for comparative study. The third question is concerned with the psychological aspects of Indian song and consequently its answer could not easily be formulated in the same manner as those relating to the other two questions, nevertheless the author has recorded her observations on this point among the Chippewa. Truthfulness and earnestness of purpose characterize this book as well as an appreciation of the people from whom the material was secured. The work has a special value to the student of musical development and presents points of interest to the ethnologist. The Bureau of American Ethnology is to be congratulated upon its entrance into an important field and particularly upon its selection of so able and scholarly an investigator

as Miss Densmore to conduct this difficult line of research.

An ample index adds to the usefulness and pleasure of the book. ALICE C. FLETCHER

Fosséis Devonianos Do Paraná. Pelo Dr. JOHN M. CLARKE. Monographias do Serviço Geológico E Mineralógico do Brasil. Vol. I., Rio de Janeiro. 1913. Pp. xx + 353; pl. I.-XXVII.

A monograph upon the Devonian of the state of Paraná, Brazil, which has been published recently by the Geological Survey of that country, constitutes a notable contribution to our knowledge of the geology of South America. The author of the work is Dr. John M. Clarke, the accomplished state geologist of New York. Long an investigator of the Devonian of that state, he has recently issued a number of monographs upon strata of the same age in both North and South America, including works upon the Lower Devonian of the Gaspé region, Canada, and upon the Devonian of the State of Pará, Brazil. To these he has now added this important monograph upon the Devonian of Paraná.

The volume consists of two parts. The first part comprises a discussion of the character and significance of the Devonian faunas of the region studied, while the second is devoted to a description of the species, with critical comments upon their relations to those of other areas.

The Devonian of America presents two broadly conceived types: a northern or boreal, confined chiefly to North America and the region north of the Amazon, and a southern or austral type. Dr. Clarke shows that the Devonian sediments found in South America, from central Brazil southward, contain an austral fauna. The latter, which differs from the boreal fauna in many respects, is a unit throughout its range, having definite and recognizable characteristics wherever found.

While the work before us is entitled a discussion of the Devonian Fossils of Paraná it is in reality a monograph upon the austral Devonian of the whole of South America. The author gives a critical discussion of the

strata and fauna of this facies not only in Paraná, but also in the state of Matto Grosso, Brazil, Bolivia, Argentina and the Falkland Islands. The work hence possesses a wide scope.

The stratigraphic succession in Paraná is as follows, in descending order: Tibagy sandstone, Ponta Grossa shales, Furnas sandstone. The strata are underlain by an ancient, crystalline complex, and are overlain by Permian Carboniferous deposits containing glacial till. A very interesting member of this series is the barren, basal Furnas sandstone, which appears to be paralleled by a similar sandstone situated at the base of the Devonian in Bolivia and Argentina. It overlies, at different places, ancient crystallines, Cambrian and Silurian strata, and hence seems to indicate a widespread transgression of the sea in South America at the beginning of Devonian time.

The austral fauna is believed by Dr. Clarke to be of Lower Devonian age, and is considered by him to have sprung from a boreal Silurian ancestry, owing its peculiarities to its development in isolation in southern waters.

One of the most notable aspects of the discussion is the fact, brought out with great clearness, that the American austral Devonian fauna finds its nearest relative in the Bokkeveld fauna of the same age in South Africa. Indeed the species of the Falkland Islands are more closely akin to those of South Africa than they are to those of the state of Paraná.

These relations lead to an interesting reconstruction of the lands and continents of Devonian time. The existence of a more or less intimate connection between Africa and South America had been foreshadowed with greater or less clearness by various writers. The author suggests that an Antarctic continent existed at that time, whose strand stretched from South Africa to the Falkland Islands and thence north into Chile and Argentina, along which the austral species migrated. A large island situated near the present state of Paraná was separated from the Antarctic continent by a comparatively narrow waterway.

A northern land mass embraced the northern part of South America and a large area on the site of the present North American continent. A land bridge is believed to have extended across the north Atlantic ocean, uniting North America and Europe, its existence being indicated by the close relation of the early Devonian faunas of Maine to those of the Coblenz district on the Rhine. It is thought probable that the center of dispersion of the austral species was located in central Africa. The division of the Lower Devonian faunas into a boreal and austral facies and their geographic distribution are explained by these facts.

The larger part of the monograph is devoted to a description and critical discussion of the species constituting the austral Devonian fauna of South America and a consideration of their relations to those of South Africa.

Illuminating comments are made upon the distinguishing characteristics of the austral types in connection with the discussion of the leading groups, the treatment of the characteristics of the trilobites being especially valuable.

The work is published in the English and Spanish languages in parallel columns. Its illustrations are of a high order of excellence. The monograph is a notable contribution to our knowledge of the geology of South America and is a credit both to the author and to the Geological Survey of Brazil.

CHARLES K. SWARTZ

BALTIMORE, MD.

SPECIAL ARTICLES

A NEW CYTOLOGICAL STAINING METHOD

DURING the course of an investigation on spireme formation and chromosome number in the pollen-mother cells of various species of *Lilium* and *Nicotiana*, considerable time was expended in testing and experimenting with stains and staining processes. In plants such as *Nicotiana*, where the chromosomes are small and the characteristic number is large (48) (24), it is desirable, especially in certain phases of the maturation phenomena, to have a stain combination which will differentiate

chromosomes sharply from the other cell material and at the same time produce a chromosomal stain translucent enough so that each chromosome in a crowded equatorial plate will stand out by itself. In the synopsis condition of the spireme, a translucent but extremely "contrasty" differentiation between the tightly massed thread and other cell materials was also thought desirable. Flemming's safranin, gentian violet, orange G combination and iron hematoxylin were usually unsatisfactory in attempting to secure the sought-for results.

Magdala-red was tested out after the methods given by Chamberlain,¹ but with unsatisfactory results. Both strong and weak solutions of the stain were used, but for chromatin and chromosome staining it never appeared to possess "body" enough to give a sharp contrast when used with anilin-blue or other blue cytoplasmic stains. After a preparation had been in the stain bath for 24 hours, the red color easily washed out during the hurried passage through acid alcohol, 95 per cent. neutral alcohol, etc., to xylol. Occasionally fair preparations were obtained, but when these were examined by artificial light, the red stain, through lack of "body," lost its brilliancy and contrast value.

The thought occurred to try mixing magdala-red with safranin O, and thus remedy the "lack of body" defect of the former and increase the brilliancy and translucency of the latter. Accordingly, a solution of safranin, made up of equal parts saturated solution of safranin O in 50 per cent. alcohol and a saturated solution of safranin in a 3-per-cent. solution of anilin oil in water, was mixed with a strong (saturated) solution of magdala red in 9 per cent. alcohol. The precipitate thrown down upon mixing the two stains was eliminated by filtering and the red solution remaining was used as the stain. Serial section preparations on the slide were allowed to remain in this stain for varying lengths of time—24 hours in most cases, after which they were treated with anilin-blue, etc., after the method as given by Chamberlain, p. 48. Many varia-

tions in method were practised; the main thing being to allow the red stain to act for a long time and the blue a very short time. The necessity of using the hydrochloric acid to bring out the brilliancy of the anilin-blue and to produce the desired contrast effect made the process undependable where good preparations were constantly desired. In other words, where only a small amount of material was to be had and every slide preparation must be made to count, as in much research work, the method was not a practicable one.

In order to eliminate the use of acid, the anilin-blue was discarded, and a saturated solution of azure II was substituted. This combination of magdala-red-safranin and azure II gave in most cases good results. A brilliant red and blue were both obtainable without the use of acid. From the solution of magdala-red-safranin, the slide was dipped directly into the azure II, allowed to remain about a second, and then rushed through the higher alcohols to xylol and neutral balsam. Variations in practise were common and it has been my intention here merely to indicate the general method. In many cases, satisfactory results were obtained by shortening the bath in the red stain to an hour or even to 30 minutes.

Preparations of reduction division stages in the pollen-mother-cells of *Lilium canadense* L. were stained as follows: cytoplasm, deep brilliant royal blue or greenish blue; spindle fibers dark blue and sharply outlined against the cytoplasm; nucleoli, usually blue in active and red in "resting" nuclei, chromatin substance (spireme, etc.) brilliant deep ruby red. Preparations of pollen-mother-cells of *Nicotiana* in early prophase have been obtained in which the vacuolated nucleoli were stained blue and little beadlike globules within the nucleolar vacuoles shown brilliant red. The chromatin is always stained a brilliant red and against the background of dark blue cytoplasm the contrast is extremely sharp. Chromosomes in those plants where their numbers are large are ordinarily counted with extreme difficulty, even under the most favorable conditions, owing to the crowding of the chromosomes on

¹"Methods in Plant Histology," 2d ed., 1905, pp. 42, 44, 47-48, 79-83.

the spindle. The process just described will, I believe, partially eliminate this difficulty, as the red is somewhat translucent and each chromosome seems to stand out by itself, even when one lies above the other. Mature pollen of *Lilium tigrinum* Ker. when fixed in Flemming and embedded and sectioned in the usual manner reacts to the process as follows: outer wall, sculpturing, etc. (perine), bright red; extine, intine and cytoplasmic structures blue or bluish green; chromatin granules and nucleoli in "resting" nuclei, red; other nuclear material blue; nuclei as a whole well differentiated from surrounding cytoplasm.

BROOKLYN BOTANIC GARDEN,
January 31, 1914

THE AMERICAN MATHEMATICAL SOCIETY

THE society held two large meetings during the Christmas holidays, one at the University of Chicago on December 26-27, the other at Columbia University on December 30-31. The New York meeting was the annual meeting of the society, and was especially marked as the occasion of the presidential address of Professor H. B. Fine, on "An Unpublished Theorem of Kronecker Respecting Numerical Equations."

Eighty members attended the four sessions. Professors W. F. Osgood and H. B. Fine occupied the chair in succession. The following new members were elected: Professor Pierre Boutroux, Princeton University; Mr. E. H. Clarke, Purdue University; Dr. W. H. Cramblet, University of Rochester; Mr. H. J. Ettlinger, University of Texas; Professor W. S. Franklin, Lehigh University; Mr. H. Galajikian, Princeton University; Professor W. W. Hart, University of Wisconsin; Mr. Barnum Libby, University of Michigan; Mr. G. W. Mullins, Columbia University; Mr. J. A. Northcott, Columbia University; Dr. Mildred L. Sanderson, University of Wisconsin; Mr. J. M. Stetson, Princeton University. Nine applications for membership were received. The total membership of the society is now 710, including 66 life members.

The Treasurer's report shows a balance of \$9,153.58. Sales of publications during the year have amounted to \$2,111.45. The library has increased to 4,902 volumes. The number of papers read at all meetings was 240.

At the annual election the following officers and members of the council were chosen:

Vice-presidents: L. P. Eisenhart and E. J. Wilczynski.

Secretary: F. N. Cole.

Treasurer: J. H. Tanner.

Librarian: D. E. Smith.

Committee of Publication: F. N. Cole, Virgil Snyder, J. W. Young.

Members of the Council to serve until December, 1916: C. N. Haskins, L. M. Hoskins, E. V. Huntington, H. L. Rietz.

The annual dinner, on Tuesday evening, was attended by forty-seven members.

The Madison Colloquium Lectures, delivered last September by Professors L. E. Dickson and W. F. Osgood, are now in press and will soon be published by the society.

The following papers were read at the annual meeting:

L. L. Dines: "Complete existential theory of Sheffer's postulates for Boolean algebras."

Arnold Emch: "Two convergency proofs."

J. L. Coolidge: "Congruences and complexes of circles."

Dunham Jackson: "On the degree of convergence of Sturm-Liouville series."

Virgil Snyder: "Birational transformations of the cubic variety in four-dimensional space."

Miss A. H. Tappan: "Plane sextic curves invariant under a group of linear transformations" (preliminary communication).

C. L. Bouton: "Explicit formulas for the inverse of an analytic transformation in n variables."

Edward Kasner: "The classification of conformal transformations."

L. B. Robinson: "Questions of logic arising from the study of systems of partial differential equations" (preliminary report).

Pierre Boutroux: "On a family of rational differential equations of the first order."

H. B. Fine, presidential address: "An unpublished theorem of Kronecker respecting numerical equations."

W. A. Hurwitz: "Note on the Fredholm determinant."

G. D. Birkhoff: "The restricted problem of three bodies."

E. V. Huntington: "On the accuracy of the contracted form of Horner's method."

O. E. Glenn: "On an analogy between formal modular invariants and the class of algebraical invariants called Booleans."

G. C. Evans: "Green's functions for linear partial differential equations of the second order, and Green's theorem."

W. R. Longley: "An existence theorem for a certain differential equation of the n th order."

W. C. Graustein: "The real congruence of complex points, planes, lines."

H. W. Reddick: "Conformal invariants of orthogonal curve nets" (preliminary communication).

W. F. Osgood: "Liouville's theorem concerning periodic functions of several variables."

L. M. Kells: "A complete characterization of dynamical trajectories in n -space."

W. H. Cramblet: "A classification of discontinuous functions and some allied problems."

J. K. Lamond: "Note on the reduction of multiple L -integrals to iterated L -integrals."

L. A. Howland: "Functions of n variables which are functions of r combinations of these variables."

J. I. Tracey: "Covariant curves of the plane rational quintic."

A. B. Coble: "Restricted systems of equations."

L. P. Eisenhart: "Transformations of surfaces of Voss."

H. Galajkian: "A type of non-linear integral equation."

T. H. Gronwall: "On systems of linear total differential equations."

T. H. Gronwall: "Extension of Laurent's theorem to several variables."

T. H. Gronwall: "On approximation by trigonometric sums."

R. D. Beetle: "Cyclic systems of osculating circles of curves on a surface."

G. M. Green: "Canonical systems in projective differential geometry, with special reference to the theory of curved surfaces."

J. H. M. Wedderburn: "A type of primitive algebra."

F. N. COLE,
Secretary

THE AMERICAN SOCIETY OF NATURALISTS

THE thirty-first annual meeting of the American Society of Naturalists was held in the Zoological Laboratory of the University of Pennsylvania on December 31, 1913. In affiliation with the society this year were the American Society of Zoologists, the American Association of Anatomists and the Federation of American Societies for Experimental Biology.

A revised constitution and by-laws was adopted with several important modifications of the old constitution:

1. The former division of the society into an eastern branch and a central branch was abolished. "Sections of the society may be organized in any locality, with the approval of the society in each case, by ten or more members for the purpose of holding meetings for the presentation of scientific papers. Such sections shall have the right to elect their own officers and associate members, but associate membership in any section shall not confer membership in the society.

2. The executive committee is permitted at its discretion to remit for any year the annual assessment of one dollar.

3. The secretary and treasurer are to be elected for terms of three years each. An additional member of the executive committee is to be elected each year to serve for three years.

4. "A committee of three, consisting of the president, vice-president and secretary, shall arrange a program for each meeting."

5. "The records of the society shall be published once every three years, beginning in 1914."

6. "The society shall reimburse the secretary for traveling and hotel expenses incurred in attending the annual meeting."

The following were elected to membership in the society: Irving W. Bailey, Harvard University; Arthur M. Banta, Carnegie Station for Experimental Evolution; Harley H. Bartlett, Bureau of Plant Industry; Charles T. Brues, Harvard University; Philip P. Calvert, University of Pennsylvania; Minton A. Chrysler, University of Maine; R. A. Gortner, Carnegie Station for Experimental Evolution; Milton J. Greenman, Wistar Institute; Robert W. Hegner, University of Michigan; Lawrence J. Henderson, Harvard University; Merkel H. Jacobs, University of Pennsylvania; G. L. Kite, Henry Phipps Institute; Ralph S. Lillie, Clark University; Clarence E. McClung, University of Pennsylvania; J. H. McGregor, Columbia University; Edward B. Meigs, Wistar Institute; J. Percy Moore, University of Pennsylvania; Alice Robertson, Wellesley College; Edmund W. Sinnott, Harvard University; Arlow B. Stout, New York Botanical Garden; P. W. Whiting, Harvard University.

The program of the morning session was as follows:

"Some Physiological Phases of the Study of Teratological Variations," by J. Arthur Harris.

"Some Physiological Observations Regarding the Genetic Factors for Plumage Patterns," by Raymond Pearl and Alice M. Boring.

"Twin and Triplet Hybrids from Wild Species of *Oenothera* with Segregation in the First Generation," by George F. Atkinson.

"The Functions of an Environment," by Lawrence J. Henderson (by invitation).

"A New Method of Analysis of Fertilization: Results and Theory," by Frank R. Lillie.

"On the Adaptation of *Fundulus* to Abnormal Salt Solutions," by Jacques Loeb. (Read by title.)

"Sex Recognition and Sexual Selection in Vertebrates," by Jacob E. Reighard.

"Endemic Species from Ancient Strands and Recently Observed Modifications of Seed-plants on the Beaches of the Salton Sea," by Daniel T. MacDougal. (Read by title.)

"Divergent Characters of the Progeny Arising from Seed Maturing in Treated Ovaries of *Scrophularia occidentalis*," by Daniel T. MacDougal. (Read by title.)

"Association of Hereditary Factors in Parthenogenetic Lines of *Hydatina*," by A. Franklin Shull.

"An Inherited Variation in the Strength of Linkage," by A. H. Sturtevant (by invitation).

"Size Inheritance in *Drosophila*," by Edward N. Wentworth. (Read by title.)

"Studies on Inheritance in Orthoptera," by Robert K. Nabours (by invitation).

"Physiological Resistance to Drought in F_2 Segregates of Certain Maize Crosses," by Herbert P. Roberts. (Read by title.)

"Partially Sterile Crosses between Species of *Nicotiana*," by Edward M. East. (Read by title.)

"Reciprocal Crosses between *Enothera biennis* and *Enothera muricata*," by Bradley M. Davis. (Read by title.)

The session of the afternoon consisted of a symposium on the subject "The Scope of Biological Teaching in Relation to New Fields of Discovery," Papers were presented by Michael F. Guyer, University of Wisconsin—Zoology; Minton A. Chrysler, University of Maine—Botany; Robert R. Bensley, University of Chicago—Anatomy and Medicine; George H. Parker, Harvard University—General Physiology.

In the discussion following the reading of the four principal papers, Drs. Goldfarb, Atkinson, Loeb, Clapp, McMurrich, Morgan, McClung, Lefevre, Reighard, Henderson and Knower participated.

The Naturalists' dinner was held on the evening of December 31, at the Hotel Walton, with one hundred and ten in attendance. The president's address by Professor Ross G. Harrison was entitled "Science and Practice."

The officers of the Society for 1914 are:

President—Samuel F. Clarke, Williams College.

Vice-president—Frank R. Lillie, University of Chicago.

Secretary—Bradley M. Davis, University of Pennsylvania.

Treasurer—J. Arthur Harris, Carnegie Station for Experimental Evolution.

Additional Members of the Executive Committee—Raymond Pearl, Maine Agricultural Experiment

Station; Ross G. Harrison, Yale University, and Elias P. Lyon, University of Minnesota.

BRADLEY M. DAVIS,
Secretary

AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE

SECTION E—GEOLOGY AND GEOGRAPHY

THE sixty-fifth meeting of Section E, Geology and Geography, of the American Association for the Advancement of Science was held in the senate chamber of the state capitol, Atlanta, Ga., December 28, 1913, to January 1, 1914. Vice-president J. S. Diller presided. Professor U. S. Grant, Northwestern University, Evanston, Ill., was elected vice-president of the association and chairman of Section E for the next meeting to be held in Philadelphia. Dr. E. H. Sellards, state geologist of Florida, was elected a member of the council, Dr. David White, United States Geological Survey, a member of the sectional committee, and Dr. S. W. McCallie, state geologist of Georgia, a member of the general committee.

In connection with the meeting the following resolutions were unanimously adopted:

WHEREAS, it is recognized that the American Association for the Advancement of Science is the great scientific organization of this country, and,

WHEREAS, it is hoped that this organization may continue to fulfil its great function as the representative of science in America,

Be it Resolved, that it is the sense of Section E, an important branch of the parent organization, that the strongest men interested in geology and geography should be urged to assist in every way possible in promoting the best interests of the general organization,

Furthermore, in the belief that these purposes can be most effectively accomplished by the co-operation of existing geological and geographical organizations, it is recommended that every effort be made to have the meetings of the Geological Society of America and the Association of American Geographers held, as frequently as possible, in connection with those of the American Association for the Advancement of Science,

It is Further Recommended, that the officers of Section E, with the approval of the council, be instructed to take such steps as are necessary to secure the desired results.

The address of the retiring Vice-president, Professor J. E. Todd, was given on the subject, "Pleistocene History of the Missouri River."

The program consisted of more than thirty papers, the majority of which dealt with the mineral resources of the southern states. It is hoped that all the papers on the mineral resources of the southern states may be published in one volume. As an aid to such publication the council voted the sum of \$200.

The titles and abstracts of papers presented before Section E are given below:

Mineral Resources of the Southern States—Distribution and Production: J. S. DILLER. (Illustrated by map and collection of specimens.)

In opening the discussion of the mineral resources of the southern states, Mr. Diller called attention to a large wall map recently prepared by the United States Geological Survey to show the distribution of the most important mineral resources of the sixteen states included in the southern section.

Of the various mineral products found in the United States only two, borax and platinum, are not produced in the southern states but, on the other hand, some of the southern states are the largest or exclusive producers of nearly a dozen substances, among which phosphate rock, manganese, bauxite, sulphur, barite and fuller's earth occur.

There are 55 different mineral substances won from the earth in the southern states, and of these a collection consisting of more than a hundred specimens was exhibited at the meetings of Section E.

Coal is the resource of first importance. The value of coal alone produced in 1912 was more than 144 million dollars, with large reserves, as shown on the map, that will last for centuries.

The total production of mineral resources in 1912 was \$401,399,483.

Nearly a score of other substances in addition to coal were produced in the same region to the value of more than a million dollars each, and while the distribution of the reserves of these resources was shown on the large map the value of the production of each during 1912 was shown on a chart.

It is expected that the map and chart will be published in connection with the volume of papers read before Section E on the mineral resources of the southern states.

The Coal Resources of the Southern States: L. C. GLENN.

This paper summarized our knowledge of the coal resources of the southern states, indicated the

trend of present developments, and showed the importance of the rôle to be played by coal in the future industrial development of the south. It was illustrated by charts and diagrams.

The Petroleum Resources of the Southern States: D. W. OHERN.

The Marbles and Granites of the Southern States: S. W. MCCALLIE.

The geographical and geological distribution, history and extent of development, physical and chemical characteristics, and commercial uses of the marbles and granites of the southern states.

The Mines and Quarries of Georgia: S. W. MCCALLIE. (Illustrated with lantern slides.)

The Piedmont Limestones of the Southeast Atlantic States: THOMAS L. WATSON AND J. S. GRASTY.

This paper discusses the occurrence and distribution, structural and age relations, composition and uses of the Piedmont limestones of the southern Atlantic states, including Maryland to Alabama. It points out their much wider distribution than has been formerly supposed and suggests their Lower Cambrian (Loudoun) age. Besides being of economic importance in many of their occurrences, these limestones form extremely important and valuable guide members in the structural work necessary to determine the stratigraphic and age relations of the associated rocks.

The Limestones of Maryland, East of the Blue Ridge: J. S. GRASTY.

This paper is devoted to the various occurrences of limestone in the Piedmont section of Maryland, and embraces a discussion of their age, stratigraphy, structure and economic importance. With the exception of the occurrences in the Frederick Valley, and in the vicinity of Baltimore, practically no attempt, based on systematic study, has been made heretofore at a correct correlation. It is believed that it can be shown definitely and satisfactorily that the limestones in the middle part of this physiographic division (Piedmont) of Maryland should be assigned to the Potsdam group of the Cambrian, though be it this is at variance with the general geological impression, which is that they are older, a view entertained, perhaps, because of their association in areal occurrence with other rocks definitely known to be pre-Cambrian.

The Slate Deposits of the Southern States: J. S. GRASTY AND J. H. CLINE.

This paper is devoted to a discussion of the more important slate deposits of the southern states, including their location, structural and age relations, quality, etc., particular attention being given to those areas occupied by active operations. This accounts, therefore, for the prominent position and greater space being given in this discussion to the occurrences in Virginia and Maryland. Slates occur also in Georgia, notably the green slate found to the north of Cartersville, and in Arkansas, Tennessee, West Virginia and elsewhere in the south.

The Cement Materials and Industry of the Southern States: THOMAS L. WATSON AND J. S. GRASTY.

The Portland cement industry in the southern states is an important and growing one. Calcareous (limestones or marls or both) and argillaceous (clays, shales and slates) materials are found in each of the southern states, being particularly well developed in those states traversed by Ordovician, Silurian and Devonian rocks. The present paper discusses the occurrence and distribution of these materials, including composition, and explains how their adaptability for use in the manufacture of Portland cement may be determined.

The Gypsum Resources of the Southern States: FRANK A. WILDER.

Gypsum in quantities sufficient to be of commercial importance occurs in Oklahoma, Texas and Virginia. In Arkansas large deposits are said to exist in Pike county but their fitness for plaster can not be positively stated. A small body of gypsum is reported from Bear Island near the post-office of Panassoffke, Fla., but this deposit is of doubtful commercial importance.

The deposits in Oklahoma and Texas are inexhaustible and consist of both rock gypsum and gypsum earths known as gypsite.

The Virginia deposit is much more limited in area and in tons available, but can probably maintain an annual output of 200,000 tons for fifty years or more.

The Virginia gypsum deposit is peculiar on account of the rather unusual relationships between the gypsum and a pronounced fault which has thrust Cambrian dolomite over the gypsum-bearing formations which we regard as of Mississippian age.

On account of the rapid increase in the use of gypsum plasters, gypsum tile for fireproofing, and

in portland cement, of which gypsum is a minor but very essential ingredient, these gypsum deposits are important factors in the development of the south.

In connection with agriculture ground gypsum is regarded as essential in the raising of peanuts and is useful in the cultivation of all legumes. It doubtless is the cheapest way to restore sulphur to the soil where this element has been exhausted; and reacts on insoluble potash compounds, rendering them more soluble.

The Gypsum Resources of Texas and Oklahoma: E. T. DUMBLE.

The location and character of the gypsum deposits of Texas and Oklahoma now being exploited commercially. Present development of the industry, and possibilities of this area. Description of other areas in Texas susceptible of similar development.

The Bauxite Industry in the Southern States: W. C. PHALEN.

The production of bauxite in the United States in 1912 was, in round numbers, 160,000 long tons, valued at approximately \$775,000. In other words, this means the production of bauxite in the southern states, for the mining of this mineral is strictly a southern industry, and such it has been since its inception in the United States.

The states which produced bauxite in 1912 are as follows: Alabama, Arkansas, Georgia and Tennessee. A deposit of the mineral is known also in Botetourt county, Virginia, but it has never been exploited. Arkansas led in the production, as it has for many years, followed distantly by Georgia, Alabama and Tennessee, named in the order of their production and the value of same.

Bauxite has a variety of uses, which are as follows: (1) As raw material in the production of metallic aluminum, (2) in the manufacture of aluminum salts, (3) in the manufacture of bauxite brick, (4) in the manufacture of alundum (fused alumina) for use as an abrasive, and (5) in the manufacture of calcium aluminate.

The use of bauxite in the manufacture of metallic aluminum is by far the most important of those enumerated above. A large part of the entire output of Arkansas is used in the aluminum industry, and the production from this state has shown phenomenal growth during recent years. When it is considered that more than 65,000,000 pounds of the metal were consumed in the United States during the past calendar year, and that this aluminum in the form of No. 1 ingots, whole-

sale lots in New York City varied in price per pound from 18½ to 27 cents, the importance of the relation of bauxite production to what promises to be one of our most important future metallic industries becomes apparent, as does also the importance of a careful search for future supplies of the mineral.

The Outlook for the Aluminum Industry in the South:

Two water-power installations of great magnitude, for the manufacture of metallic aluminum, are now in process of construction in the southern states. One of these is by the Southern Aluminum Company and the other by the Aluminum Company of America. The former, with a capital of several million dollars, has been organized by an amalgamation of foreign aluminum interests, chiefly French, together with certain metal interests in the United States, and has acquired a water-power site on the Yadkin River, near Whitney, North Carolina. The company is now engaged in the development of the property, and has plans to erect, eventually, a complete plant with large capacity for the manufacture of the metal.

In addition, the Aluminum Company of America has acquired certain riparian rights in North Carolina and Tennessee, and has undertaken preliminary developments on the Little Tennessee River near the Tennessee-North Carolina boundary. The plans contemplate a water-power development of great magnitude, together with a reduction works at Maryville, 16 miles south of Knoxville.

The consummation of two such projects as those mentioned should prove a tremendous stimulus to the search for new deposits of bauxite in the south.

The Phosphate Deposits of the Southern States:
E. H. SELLARDS.

The southern states at the present time are pre-eminently the source of phosphate rock in the United States, the total rock mined elsewhere in America being not more than 10,000 or 11,000 tons per annum. In fact this section contributes fully one half of the phosphate of the world. The statistics for 1910, the latest date at which approximately complete returns are available show the world's production of phosphate to be 5,156,671 metric tons, of which the United States produced 2,697,468 metric tons, or slightly more than one half, all of which with the exception of 11,612 tons was from the southern states. The production in the southern territory during 1911

was 3,420,774 long tons, while Florida alone in 1912 produced 2,579,865 long tons.

The phosphate deposits in the southern states are widely distributed and are diverse in their origin and manner of occurrence. Those states that are actively producing rock are: Arkansas, Tennessee, South Carolina and Florida. At least five other states, namely, Kentucky, Virginia, North Carolina, Georgia and Alabama are known to have phosphate, or phosphatic marls of agricultural value. The phosphate deposits of North Carolina and Kentucky have been mined to a limited extent. Those of Georgia and Alabama have been partially prospected, while the Virginia phosphates have been but recently discovered.

The methods used in mining the phosphate rock are, as a rule, neither complicated nor expensive. The open pit method is used for those deposits that have a removable overburden, while underground mining is resorted to only for those bedded deposits that are interstratified with other formations so that the overburden can not be removed. The chief production at the present time is from the open pit mines. After being taken from the mine the rock is washed and dried for shipment, almost one half being exported.

The Tennessee Phosphates: T. POOLE MAYNARD.

The phosphate deposits of Tennessee rank next in importance to those of Florida.

These deposits are found in what is known as the Central Basin of Tennessee, and in the valleys of the western part of the Highland rim surrounding this basin. Nodular deposits of black phosphate are found to the northeast of the Highland Rim in Putnam county.

All of the phosphates are found associated with rocks of sedimentary origin and occur in rocks of Ordovician and Devonian age.

There are three important classes of phosphate rock, while there are many characteristic differences among these classes. The brown, the blue and the white phosphate represent the three important classes. While the black rock phosphates of Putnam county are not economically important they form a fourth class.

The Salt Industry of the Southern States: W. C. PHALEN.

The five southern states which produce salt on a commercial scale, named in the order of their importance, are Louisiana, Virginia, Texas, West Virginia and Oklahoma. In the year 1912, the latest for which statistics are available, the output of salt in the states mentioned amounted to

nearly 350,000 short tons, or nearly 2,500,000 barrels, of 280 pounds each, valued in round numbers at \$725,000.

In Louisiana salt occurs in two districts, (1) in the north-central and northern part of the state in the valleys of the Red and Sabine rivers, and (2) in the southern part; the most important known deposits, and those worked at present, occurring in close proximity to the gulf coast. Rock salt is the product, mined at Weeks and Avery's islands, so-called, located in Iberia parish, very close to the Gulf of Mexico.

The only economically important deposits of salt found in Virginia occur in the southwest part of the state. These, with the gypsum deposits, extend for twenty miles along the valley of the north fork of the Holston River, and have been developed quite extensively in Smyth and Washington counties. Two gypsum plants and one alkali works, which utilizes the brines, are in operation in this area. Saltville, Smyth county, is the center of the alkali industry.

The important salt industries of Texas are located at Palestine, Anderson county, Grand Saline, Van Zandt county, in the eastern part of the state, and at Colorado, Mitchell county, in the western part. The bulk of the salt marketed in Texas is the evaporated article produced by the grainer process, but considerable also comes from the inland salt lakes in the western part of the state and from the lagoons along the southwestern coast.

In West Virginia the industry is confined to the Ohio River Valley and to the valley of the Kanawha River, a few miles above Charleston, the state capital. The product is evaporated salt produced by the grainer process. Bromine and calcium chloride are also produced on a considerable scale, in connection with the manufacture of salt.

In Oklahoma the salt industry is small, and is confined to the salt plains in the southwestern part of the state.

The Asbestos Deposits of Georgia: OLIVER P. HOPKINS.

Asbestos representing three modes of occurrence is found in Georgia. Chrysotile, occurring in serpentine derived from peridotite, is present in insignificant quantities in a few localities where it gives no promise of commercial importance. Asbestos of the amphibole variety in slip-fiber veins occurs at widely distributed points over the Piedmont area of the state; while mass-fiber asbestos, which represents the important deposits from a commercial point of view, is restricted, in

general, to the belt of peridotites and pyroxenites which cross the state in a southwest direction from Rabun county to Harris county, but is relatively most important in Rabun, White and Habersham counties than any others. Judging from the field relations and the microscopic study, it has been concluded that the mass-fiber anthophyllite has been derived from enstatite-olivine rocks.

Mass-fiber asbestos, owing to the nature of its occurrence, is capable of being mined very economically, but owing to the slight demand for the material little is being put on the market at the present time. With a good demand for the material at from \$10 to \$12 per ton a number of deposits in this state could be worked at a profit and a large amount of asbestos could be put on the market.

The Production of Fuller's Earth in the Southern States: E. H. SELLARDS.

Fuller's earth is a clay which has the property of absorbing basic colors and removing these from solution in animal, vegetable and mineral oils, as well as from water and certain other liquids. In commerce the earth finds its chief use in clarifying oils, although it has in addition a number of minor uses.

Fuller's earth, like other clays, is complex and consists not of a single mineral, but of a variety of minerals, the mineral particles being mixed in different earths in widely different proportions, resulting in a varying chemical and mineralogical composition. The ultimate analysis does not differ materially from that of other clays. The properties of the earth arise apparently from the physical condition of the clay and can be detected only by a filtering test by which its practical utility in clarifying oils is determined. Various other properties are assigned to fuller's earth but all, aside from actual bleaching tests, are so variable or are common to such a variety of clays as to be of only secondary value in identifying fuller's earth.

Fuller's earth is mined chiefly by the open pit method, the overburden being removed and the earth dug by pick and shovel. It is then crushed, dried, ground, bolted and sacked for shipment. That intended for clarifying mineral oils is ground to pass 30-60 or a 60-80 mesh sieve while that intended for clarifying edible oils is usually ground to 100 mesh. The action of fuller's earth in clarifying oils is believed to be due chiefly to colloidal silica present in the clay. It is a notable fact that clays suitable for clarifying mineral oils

are in some cases at least unsuited for use on edible oils and the converse is also true. Most fuller's earth gives a taste and odor to edible oils, but it is now known that this can be removed by blowing dry steam through the refined oil heated above the boiling point of water. Some fuller's earths have so rapid an oxidizing effect on edible oils that the mass takes fire when air is blown through to force out the oil remaining in the earth after treatment. This defect in the earth can not at present be remedied.

In the United States fuller's earth was produced during 1912 by seven states. Of these one, Massachusetts, is an eastern state; two, California and Colorado, are western states; and four, Arkansas, Florida, Georgia and Texas, are southern states. The total output of fuller's earth in the United States during 1912 according to the United States Geological Survey was 32,715 tons, all of which with the exception of one or two thousand tons is from the four southern states named, by far the largest part, probably as much as 25,000 tons, being produced in Florida.

The Clay, Brick, Pottery and Bauxite in Tennessee: WILBUR A. NELSON.

A general account of the clay resources of Tennessee, giving the location of ball-clay deposits in west Tennessee, and some recent tests made by the Tennessee Geological Survey. Also a general account of the brick and pottery industry, and a brief description of the bauxite deposits of east Tennessee.

The Tripoli Deposits of Tennessee: L. G. GLENN.

Extensive deposits of tripoli are found in the Watanga shales of the Cambrian. They are the result of the leaching under surface influences of siliceous-argillaceous limestone beds, one of which is some forty feet thick and of very considerable length. The beds, of which six are known, dip at high angles. The depth to which they have weathered is not determined but is known to exceed fifty feet. The material is very similar to the tripoli now marketed for general scouring and polishing purposes.

The Occurrence, Conservation and Utilization of Certain Non-metallic Minerals of the Southern States: JOSEPH HYDE PRATT.

The Iron Ores of the Southern States: WILLIAM B. PHILLIPS.

The Zinc Deposits of Tennessee: A. H. PURDUE.

This paper gives the location of the zinc ores, extent of their area, occurrence and instructions as to prospecting; gives a brief history of zinc

mining in Tennessee, with prominent mention of the old Embreeville mine, and also describes the present mining conditions and output.

The Copper Resources of the Southern States: C. H. GORDON.

This paper is an attempt to present briefly the present condition of our knowledge of the copper resources of the southern states.

Copper minerals are of widespread and general occurrence both in geographic position and in geologic age but the deposits of known age that have made important contributions to the country's output can be referred to four periods which in general correspond to periods of igneous activity, viz., the Precambrian periods, the Paleozoic era, the Mesozoic era and the Tertiary period. The chief Appalachian deposits belong to the Paleozoic era and constitute practically all the known deposits referable to this era.

As to their geologic relations the deposits of the southern states may be classed under four groups as follows: (1) Lenticular deposits in schistose rocks. These include mainly deposits of the sulphides of iron, copper and zinc in lenticular bodies in schistose rocks comprising in part altered sedimentary rocks and in part altered igneous masses of basic and acid types. (2) Deposits in fractured and brecciated zones. These include deposits in fissure veins and deposits formed in brecciated zones. (3) Deposits of native copper and cuprite disseminated in igneous rocks. Under this head are grouped deposits in which the copper occurs chiefly in the form of cuprite and native copper distributed along joint planes and crevices, and as disseminated grains in igneous rocks of basaltic type. (4) Disseminated deposits in the Red Beds of the Triassic area. These consist for the most part of films and thin coatings of malachite on joint faces and grains of sulphide and phosphate disseminated through the rock.

The chief deposits of the southern states belong to the first and second classes. Ninety-five and one half per cent. of the production of these states comes from the district of Ducktown in Tennessee. Of the remainder over two thirds is recovered as a by-product in the dressing of the lead ores of Missouri.

Physiographic Conditions that have Contributed to the Making of Atlanta: COLLIER COBB.

A Biological and Physiographic Reconnaissance of the Okefenokee Swamp: J. CHESTER BRADLEY. (Illustrated with colored slides.)

The Development of Some Lake Beds in Florida:

E. H. SELLARDS.

This paper relates to the origin of the basins of the large flat-bottomed lakes found throughout certain parts of interior Florida. These lakes are often of considerable size, although relatively shallow as compared to their areal extent. Moreover they are variable in character. Under normal conditions they are clear water lakes abounding in fish and the favorite haunt of the wild duck. They have, as a rule, no surface outlet, yet from many of them the water has at times disappeared in a manner seemingly inexplicable. Among the largest and best known examples are: Lakes Lamonia, Jackson and Lafayette in Leon county; Micoosukie in Jefferson county; Alligator in Columbia county and Alachua in Alachua county.

These lakes occupy basins which have worked their way down through the surface sands and clays probably of the Alum Bluff formation to or nearly to the underlying limestones which are of either the Chattahoochee or the Vicksburg formations. The beginning of each basin dates from the formation of a sink making an opening through to the underlying limestone, thus diverting the surface drainage to a subterranean course. The small basin resulting from a single sink is enlarged by the formation of additional sinks, this process being promoted by the considerable amount of the surface water that is admitted into the underlying limestone, particularly when the sink has formed in the valley of an existing stream. The depth of the basin is limited by the underground water level since the streams can not well carry away the residual material below this level. As a matter of fact the basins approach but do not quite reach the underground water level.

The ground water level is not stationary but is subject to seasonal and periodic variations, as well as to variation in geologic time. The seasonal fluctuation is due to the variation in rainfall during the wet and dry seasons. The periodic variation is due to the more or less regular periods, often of some years duration, of deficient or of excessive rainfall. The gradual lowering of the underground water level during geologic time, which is due to the downward cutting of stream channels which serve as an outlet, affects the life history although not the observed behavior of the lakes. The seemingly sudden emptying of the lakes is in most cases due actually to the water having gradually run out into the underlying limestone because of the ground water level having

been lowered by prolonged drought. New sinks are likely also to form at this time since the lowering of the underground water withdraws the support from the surface materials which are then no longer able to support their own weight and hence break through to cavities in the underlying limestone. These new sinks when formed facilitate the emptying of the lakes.

A New Gypsum Deposit in Iowa: GEORGE F. KAY.

In this paper some interesting facts are presented with reference to a gypsum deposit recently discovered at Centerville in southern Iowa. The gypsum is of Mississippian age and is associated with anhydrite. Whether or not the gypsum will prove to be of economic importance has yet to be determined. The evidence indicates that the deposit may be extensive and the gypsum is of good quality. The relation of the anhydrite to the gypsum and the relative amounts of the two minerals will have an important bearing upon the value of the deposit for commercial purposes. The fact that the deposit is more than 500 feet below the surface and the presence of large amounts of artesian waters are factors unfavorable to the mining of the gypsum. On the other hand, the deposit is well located with regard to fuel and transportation, and it is fair to assume that if gypsum products were made in this part of the state a good market for such products could soon be developed.

The Development of Some Underground Streams:

EDGAR H. WEBSTER.

A Comparison of the Ordovician Section of Southwest Virginia, with that of New York: S. L. POWELL.

In view of statements not infrequently made to the effect that the Ordovician of Virginia and the South in general can not be correlated with the New York section, and in view of the fact that in southwest Virginia, in the vicinity of Salem, there occurs a continuous, unbroken section of Ordovician strata about four thousand feet in vertical thickness, very favorably disposed for observation, and as the locality is intermediate between the extremes heretofore most carefully studied, detailed work was undertaken for purposes of comparison with the standard sections north.

The results show that the correlation can be made, and that in almost every detail, including the divisions of the Beekmantown (Califerous) established by Brainerd and Seely of Vermont. Without going into detail here, the main difference

in the Ordovician is at the top and near the bottom of the section. The alternating red and greenish yellow shales and sandstones (Bays) just beneath the Medina sandstone, occupying the position of the Juniata in the north, are here very fossiliferous, whereas in Pennsylvania and New York they are practically barren of life forms. Here it carries *Orthoceratites*, *Gasteropods*, *Brachiopods*, etc., in great abundance. The stratum here measures about eighty feet whereas in the north it is several hundred feet thick. The Hudson River is virtually the same as north. Just above the Trenton, however, occurs a heavy stratum of alternating sandstone and shale, Tellico of the south. The upper Trenton is massive rather impure light blue limestone, passing into thin bedded dark to black limestone with some shales intervening. The middle Trenton is characterized by a development of several hundred feet of black shale (Athens Shale) carrying *Trilobites* and many forms of *Graptolites*, among which are the whorled type described by Ruedemann from northeastern New York. This is followed by the Black River limestone, identical in almost every respect, lithologically as well as in fossil content, with that of New York. The same is true for the Birdseye beneath. The Birdseye terminates in a six-foot stratum of brecciated conglomerate, with fragments of limestone and chert ranging in size from one half inch to fifteen inches in diameter. The Chazy, which follows, agrees in its lithology and fossil content with that of Vermont, terminating in a ferruginous sandstone, which corresponds in position and character with the Isle La Motte sandstone.

Detailed work in the Beekmantown below has not as yet been completed, but thus far the divisions established by Brainerd and Seely of Vermont with their characteristic boundaries and fossils are believed to have been identified.

The "Undagraph," Its Use for the Study of Microseisms: OTTO KLOTZ. (Illustrated.)

Recent Backward Extension of the Life Record in Geologic Time: CHARLES KEYES.

The differentiation of life on our globe prior to the stage represented by the *Olenellus*, or Early Cambrian, zone, the oldest phase with which we have been acquainted, has lately passed from the realm of pure speculation to that of direct observation. The wide interest aroused by these recent discoveries of abundant well-preserved organic remains in rocks of undoubted pre-Cambrian, and

hence pre-Paleozoic, age is secondary only to the enthusiasm produced a few months ago by the actual location of the fossiliferous horizons in the general geological column. As definitely determined these oldest fossil-bearing levels are stratigraphically more than two miles beneath all other known horizons yielding traces of life. The revelations, of course, materially modify all our previous notions on the subject. They open up a more inviting field of investigation than awaited paleontologists when the Paleozoics first revealed their secrets. Between the bottom of the Paleozoics and the old Azoic gneisses, as usually represented in the text-books of the science, we may now insert the complete schemes of two great fossiliferous successions each of greater stratigraphic and taxonomic importance than that of the entire Paleozoic sequence as now known.

ATLANTA MEETING OF SECTION G

At 2 P.M., Tuesday, December 30, the meeting of Section G was called to order by the chairman, Professor H. C. Cowles. In the absence of the secretary, Professor W. J. G. Land was made secretary *pro tem*. The following officers were elected. For member of the sectional committee for five years, Dr. D. T. MacDougal; for member of the council, Dr. C. Stuart Gager; for member of the general committee, Professor D. M. Mottier.

The Sectional Committee recommended and the association elected Professor G. P. Clinton, of New Haven, as vice-president and chairman for the Philadelphia meeting.

The following papers were read:

"The Evolution of a Botanical Problem: The Discovery of Sexuality in Plants," address of the retiring Vice-president, Duncan S. Johnson.

"The Water Requirements of Plants," by Lyman J. Briggs and H. L. Shantz.

"Samoan Vegetation," by W. J. G. Land.

W. J. V. OSTERHOUT,
Secretary

SOCIETIES AND ACADEMIES

THE NEW ORLEANS ACADEMY OF SCIENCES

THE regular monthly meeting of the Academy was held at Tulane University, on Tuesday, January 20. Dr. Isadore Dyer, the president, presided and there was a large attendance of fellows and members.

The subjects of the meeting were: (1) a paper on "The Passive State of Metals," by Dr. B. P. Caldwell, professor of chemistry at Tulane. The speaker reviewed the different theories which have been brought forward to account for the facts of passivity from the time of Keir to the present, pointing out the facts in support of, and in opposition to, each theory. He also called attention to certain especially peculiar phenomena attendant upon the processes of passivating and activating, and in closing pointed out the industrial importance of scientific study of the problem of making iron and metals in general more resistant to corrosion.

The second paper was read by Dr. W. L. Owen, of the United States Bureau of Agriculture, upon the problem of the maintenance of soil fertility. The speaker brought out the fact that the problem seemed much more complex to-day than it did when Liebig made his celebrated contribution to the subject. The problem of the future, according to the speaker, will concern itself more with the detection of soil toxins and the best means of stimulating the various groups of soil bacteria than in the increased use of commercial fertilizers.

There was some discussion at the conclusion of these papers, in which Drs. Gustav Mann, C. C. Bass and J. H. Clo and other speakers participated.

R. S. COCKS,
Secretary

THE BOTANICAL SOCIETY OF WASHINGTON

THE ninety-fourth regular meeting of the Botanical Society of Washington was held in the Assembly Hall of the Cosmos Club, at 8 P.M., Tuesday, February 3, 1914. Messrs. Raymond B. Wilcox, Arno Viehoveer and Henry Pittier were elected to membership.

The scientific program was as follows:

Brief notes and Reviews of Literature.

Dr. David Griffiths reviewed a prospectus of a stock company which has been organized in Australia for the purpose of eradicating the cactus, which is there considered a serious pest.

Mr. S. C. Stuntz called attention to the return from Brazil of Mr. A. D. Shamel, who has been there with Messrs. Dorsett and Poponoe, who are studying methods of tropical fruit culture and introducing the varieties that may be of value in this country. Mr. Shamel brought back over 1,100 photographs which have thus far been taken by them, and prints of these will soon be available for study at the Office of Foreign Seed and Plant Introduction for those who are interested.

A Report on the Atlanta Meeting of the Botanical Society of America: DR. R. H. TRUE.

Dr. True gave a report on the attendance at the meetings and number and character of the papers read before the different sections, with special notes regarding those of a botanical character.

The Relation Between Transpiration and the Absorption of Inorganic Constituents by Plants:

DR. H. HASSELBRING.

Published in *Bot. Gaz.*, 57: 72-73, January, 1914.

A Fertile Hybrid Between Tripsacum and Euphonia: G. N. COLLINS. (With lantern.)

To be published in the *Journal of the Washington Academy*.

An Attempt at Revegetation on Kodiak Island, Alaska: DR. WALTER H. EVANS.

The conditions on Kodiak Island following the eruption of Mt. Katmai in May, 1912, were described and an account was given of experiments in restoring the meadows and pastures of the experiment station on that island.

The level land was covered with the ash, or, more correctly, the debris from the explosion, to a depth of 12 to 14 inches, and practically all vegetation was destroyed. The only natural revegetation was where hummocks of earth brought the original soil nearer the surface or where plants came through cracks that formed in the deposit during the summer season. In these places fireweed, *Epilobium angustifolium*, and Alaskan red-top, *Calamagrostis langsdorffii*, have come up quite abundantly.

In gardens and wherever an especial effort was made to mix the deposit with the underlying soil, better growth was reported than normal, the ash appearing to have been of benefit, probably by reason of the improved physical condition of the soil.

STUDENT MICROSCOPES

We have written on this subject many years and as it continues to gain in importance so shall we consider it our task to familiarize the instructors with the part which we assume in the equipment of all science laboratories.

To read our literature one cannot fail to observe that new ideas in microscope construction are constantly coming in the new Leitz models introduced from year to year, and these same improvements incorporated into microscope models of earlier design.

Our claim to highest perfection in student microscopes is embodied in

MODELS II L AND II S "LEITZ"

which can be seen in use in the student laboratories of the leading universities. These models serve their purpose indefinitely, not only temporarily as do so many of the models offered in competition. Microscopes II L and II S need only an introduction in any laboratory, to lead to their being adopted as a standard for quality, perfection and durability.

At the time of this writing an order reaches us for one hundred and fifty of these same models, from a state institution. This is by no means their initial order for Leitz microscopes. Furthermore, this is not an exceptional instance, but cited at random, as convincing proof of prevailing opinion.

Stand II L is not a recent model and therefore a familiar type found in laboratories where a microscope is desired for considerable high power work, where a fine adjustment of **extreme sensitiveness** and **slowest motion**, combined with **greatest durability**, is required. The Leitz Side Fine Adjustment, the "crowning feature of Leitz Microscopes," more than fulfills these requirements.

Stand II S with Ball Bearing Fine Adjustment on side

Stand II S is our latest model and differs from II L only in the fine adjustment. **The Ball Bearing Fine Adjustment, of which we are the originators** is of the same degree of careful mechanical construction as in the former adjustment and equal in durability. Not being so slow in motion, however, it becomes ideal in connection with a microscope for routine and class work.

Remember:

Stands II L and II S cost but little more than other microscopes

and the investment will be more than repaid through a continual satisfaction in their use.

Stand II L with Side Fine Adjustment by means of Worm Screw "Continuous Motion."

RECENT BOOKS

Animal Communities in Temperate America.

By VICTOR E. SHELFORD, Instructor in Zoölogy in the University of Chicago.

This volume by Dr. Shelford presents the principles of field ecology, illustrated by the more widely distributed animal habitats of the eastern half of temperate North America, and the aquatic habitats of a much larger territory. Six chapters deal with general principles.

In several chapters the animal communities of lakes, streams, swamps, forests, prairies, and various soils and topographic situations are considered from the point of view of modern dynamic ecology. A very valuable feature of the book is the three hundred figures of widely distributed animals chosen to represent the chief types of animal communities and their characteristic modes of life.

380 pages, 8vo, cloth; price \$3.00 (weight 44 oz.).

Artificial Parthenogenesis and Fertilization.

By JACQUES LOEB, Member of the Rockefeller Institute for Medical Research.

This new work presents the first complete treatment of the subject of artificial parthenogenesis in English. Professor Loeb published four years ago a book in German under the title *Die chemische Entwicklungserregung des tierischen Eies*. Mr. W. O. R. King, of the University of Leeds, England, translated the book into English, and the translation has been revised, enlarged, and brought up to date by Professor Loeb. It gives, as the author says in the preface, an account of the various methods by which unfertilized eggs can be caused to develop by physico-chemical means, and the conclusions which can be drawn from them concerning the mechanism by which the spermatozoon induces development. Since the problem of fertilization is intimately connected with so many different problems of physiology and pathology, the bearing of the facts recorded and discussed in the book goes beyond the special problem indicated by the title.

UNSHUNTED HOT-BAND AMMETERS

Made by HARTMANN & BRAUN

The Hot-band Ammeters made by Hartmann & Braun are especially suited for wireless work. Entire current passes through the instrument, eliminating the errors caused by the use of shunts. Indications are correct on frequencies as high as 1,000,000 oscillations. Portable forms are made up to 100 amperes capacity, while switchboard types are available up to 300 amperes.

Hartmann & Braun also make an excellent line of Hot Wire Wattmeters and Milliammeters, which are valuable for wireless work in connection with Wavemeters, Platinum Iridium Hot Wire Voltmeters, and Ammeters, in portable and switchboard types.

Write for Bulletin W. T., giving full details.

THE PROVINCIAL UNIVERSITY IN CANADIAN DEVELOPMENT¹

THE problems involved in the development of Canada are not to be compared with those of any other country in the world. Her remoteness from the center of imperial government and her close social and business association with the friendly neighbor to the south, who of necessity can not understand her relations to the mother country, have not served to disturb her poise.

To develop, round out, fuse and nationalize Britain has taken two thousand years. In the making of that portion of Greater Britain, the Briton, the Piet, the Scot, the Roman, the Saxon, the Jute, the Angle, the Norman and even the Spaniard, since the time of the Armada, have been fused, whilst the Jew has furnished an increasingly important strain for the past thousand years. Nor has Germany failed to make her contribution to our highest social and governmental strata. The facilities, however, for rapid nation-building have increased by leaps and bounds, of which the chief is ease of transport and communication.

In the United States, the world has had the opportunity to see the creation of a nation in a day, where the scores of elements have been garnered in the four corners of the earth from those countries whose centuries of growth have brought overcrowding and in some have given birth to intolerable conditions.

In Canada, the same conditions obtain as are to be encountered in the United States, with the difference, however, that the Anglo-Saxon dominates, British tradi-

¹ An address given on the occasion of the inauguration of the first President of the University of Manitoba, at Winnipeg, on November 19, 1913.

tion governs and her law and rule are paramount. Also inevitably Canada must afford ultimate relief from the overcrowding of her older neighbor.

The problem of Britain, Germany or Japan is quite another story. These nations in their growth, as well as others which can be easily called to mind, are endogenous, that is, in them development proceeds from within. In the United States and Canada and those countries which are being populated more largely by the immigration of other peoples than by that natural increase which depends upon birth rate, there is crying need of certain nation-building mechanisms, whose function shall be to secure rapid fusion of bloods, and formulation of common standards which shall serve to develop a people of the highest type. In Canada, the ideas and ideals are grown from British seed and transplanted to new-world soil but must have engrafted upon them an international viewpoint suited to her many peoples in order that the full fruition of Canadian national efficiency may be her contribution to the empire.

This very difference in population assets, which in Britain are fixed and in Canada fluid, is a very real difficulty, although by no means insuperable.

The diffusion of accurate information from each portion of the empire to every other part will enable each of the dominions to effect sufficient modification in British procedure and viewpoint for local needs, without fear of being regarded either as lacking in loyalty or too widely divergent from tradition. Canada's task is that of constructing a nation almost "while you wait," which must, however, be a part of that *supernation* upon which the sun never sets. Hers is a constructive problem. She builds anew and does not have to dwell in chaos amid the litter of

tearing down whilst she rebuilds her whole national fabric. She will therefore do wisely to profit by the experiences of the older nations in order that there may be no need of the uneconomic and tragic task of reconstruction.

In the development of Britain, undoubtedly her peregrinative propensity involved in sea supremacy has been the natural and rational outcome of her geographical position. In this, our parent country affords us the best possible example in the matter of profiting from the experiences of other peoples and the adaptation of their methods to British needs, whilst at the same time she has given to the world British standards of fair play, established justice, and carried law and order into the Seven Seas.

Japan at the present moment is perhaps the most conspicuous example of what a definite coordinated plan of procedure may do in hastening the solution of very real and pressing economic, social and political difficulties, dependent upon increase of population and limited territory. Her sons are models of patriotism in their eager willingness to expatriate themselves for years in order to bring back to Japan those up-to-the-minute scientific and cultural stimuli needed for national metamorphosis. Apparently, she seeks to be the carrying nation of the Pacific, realizing, as Britain did before her, the real power and opportunity which lie in the assumption of such a function.

She is developing an educational system of which her university is an important part. She is training her youth, not only by manning her schools and universities with the best obtainable talent of other countries, but in every land and in almost every university are Japanese who are gladly sacrificing years of their lives in order to bring home what she needs at this critical period. Her amazing success in the

development and maintenance of physical fitness in the avoidance of disease and in the care of her wounded during the Russo-Japanese war startled the world. It is, however, only one of the many examples of the phenomenal advance which has resulted from her most painstaking and patient efforts to carry out, systematically and in detail, a carefully designed and fully matured plan for securing national efficiency.

The value of such a far-sighted nationwide scheme is to be seen in the present most wonderful economic and social revolution which is being effected in Germany. The careful preparation in advance of a program by which the state recognizes and provides education in all its stages and in all its phases, from the highest cultural development to the most practical industrial training, is to be credited with the marvelous progress of this country.

It does not suffice to leave to private effort and volunteer organization the provision of sources of culture and scientific study which may or may not become *directly* related to the practical upbuilding of a people. If the state assumes any responsibility at all for education, scientific research, investigation, cultural development and art, she should coordinate her various mechanisms, and see that all possible avenues are opened for the *direct* as well as the *indirect* benefit of the whole people.

Great Britain, though somewhat late in recognizing that education is apt to lag behind instead of dominating social and industrial relations, is rapidly establishing provincial universities and agricultural and technical schools which are being extended in scope and increased in number. The prestige of having the finest cultural centers in the world without available channels for conveying direct to all the peo-

ple the knowledge of the few, was not meeting her needs.

The development of the state university in the United States and its orientation in the educational system of the commonwealth has been the cause of amazement to the whole world, including some of the older seats of learning in that country itself.

Beginning with Ontario, Canada is developing a system of state or provincial universities. She has every reason to feel proud of those provinces which have taken up this logical and natural as also inevitable function, and no university in America, whether supported by state or private endowment, has developed finer standards or achieved more real success than the University of Toronto.

In order to meet her many peculiar conditions, some of which have been already mentioned, Canada must bring to her work all the help which can be afforded by the other nations of the world. She draws her citizens largely from them. Some of these are capable of adding immediately to Canadian cultural and scientific prestige. Many, however, must be regarded simply as raw material, brought to Canada for the purpose of their individual and collective improvement.

To hasten the process of Canadianizing them and to derive the greatest national profit from the best and the worst in the shortest possible time are most important.

If we are not satisfied to wait until the second or third generation for results, we must provide leaders who know conditions in both lands. The best brains of their countries may be used to leaven our land. They and Canada's strongest sons who have been trained in both lands are needed in our universities and schools.

The example of Japan in this matter is worthy of our emulation if we are to take and keep our place with other nations and

bring to the empire what she has a right to expect.

There is no one force which can do more in this important undertaking than the provincial university when properly articulated with the other educational units of each province, if these resulting provincial systems are properly coordinated and organized into a workable national mechanism.

CONSERVATION OF NATIONAL RESOURCES

It is most important that we appreciate our responsibilities for the heritage which has been given us. We must not be intoxicated by the realization of nature's prodigality. In the exuberance of our youth, we must not sow national wild oats for our children and children's children to reap.

We must conserve our national resources intelligently, which means that we must use and not abuse nature's gifts to us. We can well take warning from the experiences of the United States, where it is being found necessary to hold annual conservation congresses, one of which is now in session at Washington, D. C. At this congress, forest conservation will receive first attention, the desire being to specialize on some one phase of the conservation program at each meeting, for the purpose of achieving more lasting results. In the call issued for this congress, the following announcement is made:

The fifth National Conservation Congress is to be devoted largely to forest conservation, because of the national importance of the subject in its many phases. Public interest is involved, because upon the proper solution of the various problems depends the cost of the wood without which our civilization would decline; the perpetuation of the timber supply; the development of hydro-electric power; the utilization of non-agricultural lands; the availability of water for irrigation; the preservation of forest areas for health and recreation; and many other developments essential alike to

every citizen from the lumberman to the man who owns neither a tree nor a foot of land.

The congress will endeavor to diffuse more information and develop better methods for the prevention of forest fires which cause such tremendous loss of life and of property valued at over fifty million dollars annually, and which also damage the soil, the water and the young timber growth. The study of forest insects is important, since they destroy enough timber every year "to finance the construction program of the navy." The relation of floods to forest denudation, which is in part responsible for the disasters of the current year, will be studied.

The need of knowing exact conditions so as to avoid the use each year of three times the annual timber growth is apparent, particularly when we realize that only forty to seventy per cent. of each cut tree is utilized, while fires are destroying annually the equivalent of this growth. The use of preservatives for the treatment of wood with the view of prolonging its life when used in constructive work is important because through it we have promise of reduction in forest consumption and the possibility of increasing supply by utilizing inferior species of woods at present not available. Another object of the congress is to meet the need on the part of the public for a safe national forest policy against which there seems to be strong opposition.

These details are cited, not because they constitute Canada's most important national waste, but because it is the one which at this moment is receiving recognition and study by our neighbors.

The conservation of the soil elements, the utilization and preservation to the people of water powers, mineral wealth and above all, that chiefest national asset, the public health and human vitality, surely constitute a present-day responsibility, if the

Canada of the future is not to curse the Canada of to-day.

Our land is full of opportunity. Our spaces are wide. Citizens of less fortunate countries, which have wasted their opportunities and shirked their responsibilities until too late, have turned their eyes towards Canada.

Canada has a right to expect, both from her own and her foster children, that they shall use but not abuse their unrivaled chances for national and world betterment. We shall be wise if we see and provide in time the proper mechanisms for harmonizing rapid development with proper conservation of resources before we are fighting for the room and the right to breathe by reason of our overcrowding when we should be unable to think clearly and act intelligently and realize too late that in our short-sightedness we have made unwarranted overdrafts on nature's storehouse.

Facilities for rapid transit and free communication have enabled Canada to have at her command, while she yet has room, all the equipment evolved by the older and more crowded nations. Pioneering in the year 1913 is indeed "*pioneering de luxe*." This, whilst a matter of self-gratulation for increased opportunity, brings also added responsibility to our generation.

The necessity for the provision of national and provincial facilities for seeking out, accumulating, weighing, standardizing, adapting and diffusing knowledge require no argument: in fact, the newer provinces in the middle and far west have already anticipated this need and we are now met to celebrate an important step in the development of our prairie province from whose ample bosom is derived that sustenance upon which so many in this and other lands have come to depend.

The Canadian government has not been blind to the value of such knowledge to the

people. The provision of a fund of ten million dollars to be distributed throughout the Dominion for the benefit of agricultural instruction is a splendid national investment. This far-sighted policy under the direction of such wise leaders of Canadian progress as Dr. C. C. James, will bring much that is needed, not alone to the agricultural interests, but to all of us.

SCOPE, VALUE AND COST OF PROVINCIAL UNIVERSITIES

In the consideration of the function and scope of a provincial university, we should carefully consider the end sought, the benefit to be derived, the means available and the cost of installation and operation. At the present day we are not staggered when confronted with the necessity of spending hundreds of millions of dollars on railways, whose construction is necessary to open up new lands. We pledge our own generation and our children to the payment of vast sums for advantages which sometimes remain problematical for years. We see the need for tremendous capital investment in the matter of mines when sometimes many years elapse before production yields satisfactory dividends. The dividends to be paid by our educational system are not all to be expressed in terms of dollars and cents, but they are sufficiently obvious to induce those states which have had most experience to invest more deeply every year.

I had the honor to deliver the second annual opening address before the faculty of science of the University of Manitoba in October, 1907, at which time I spoke upon "State Responsibility in University Education." On that occasion I gave the available figures for capital and maintenance expenditures in certain of the state institutions in the mid-western portion of the United States. At that time, Wisconsin

was spending for all purposes something over one million dollars per annum. Minnesota's outlay for current expense was over \$650,000 per annum. Illinois had available considerably over two million dollars for all purposes for the biennial period.

Only six years have elapsed and yet for the current year 1913-14 there is being expended by each of the three state universities—Minnesota, Wisconsin and Illinois—in round numbers, two million dollars per annum for current expenses, which excludes not only building, but equipment outlay. This increase of approximately three hundred per cent. in six years in expenditure undoubtedly would not be made were it not for the fact that those three states are convinced that they are receiving satisfactory dividends on those combined annual outlays of over six million dollars. That they are being repaid in many more directions than they realize during those early years seems likely, because in the modern university, as in a railroad or other important public utility, the initial cost of installation and operation, as also of extension, must inevitably be very much higher in relation to efficient service than in later years.

For the proper fulfillment of her function of developing leadership in every phase of social and economic development, the provincial university must of necessity keep pace with all human knowledge and add her share to the sum total. When we remember the additions which have been made to our armamentarium in our own generation, we shall be prepared to plan generously for the future.

It requires no mental effort, however, to understand that in order to prepare as well the youth of to-day to meet his responsibility as we were prepared to meet ours, a greater range of teaching and experience must be provided because of the added knowledge of one generation.

The standpoint of the youth of to-day is not very different from that of our own. He believes that his capacity is greater and his viewpoint wider than those of the preceding generation, just as we unblushingly admitted our superiority over our predecessors. Even admitting his increased mentality for the sake of argument, we realize that the youth of to-day can not avail himself of all of our sources of information as well as those which have been discovered since his time. Notwithstanding the increase of human longevity, we are not yet warranted in insisting that thirty or more years be expended in preparation for an active working period of a like term.

Nevertheless, universities must maintain all the departments of real knowledge which were available to earlier generations whilst developing those of importance to the present and coming generation. If she is to be the chief mechanism for the diffusion of knowledge, she must be the leading explorer in unknown fields in order that our stock of knowledge be increased. Upon her rests the responsibility for finding out and bringing over from older and other lands, all that is worth while. She, too, must take a leading place in the investigation of local resources and develop methods for their more intelligent utilization. Thus each province will come to know the resources of other lands and of other provinces and at the same time be in a position to afford exact information and the best possible service to others who need what she has to give.

Canada needs experts in special lines, some of which deserve mention.

HOUSEHOLD ADMINISTRATION, HOME ECONOMICS AND DOMESTIC SCIENCE

These are terms with which we are all familiar and indicate that this generation is waking up to the need of special train-

ing for the most important work in nation-building. The successful making and keeping of the home is indeed a profession which requires the most careful training of women of the best moral fiber and the highest mental equipment. The housekeepers of our land are those who perhaps spend the bulk of the nation's money. Yet in the past there has been little in the way of careful training for this most important economic work. The home-keeper is not less important in our social development. We leave to our women very many non-descript duties included in the care of the home. She it is who knows all details of the children's physical and intellectual progress. She has accurate information about our schools. To her we turn when problems of civic house-cleaning and house-keeping arise through man's negligence. It is, therefore, most appropriate that at length we are providing practical as well as cultural training in order to enable woman to meet some of her obligations.

Universities must train our leaders in women's work and provide facilities for research in the science of home-making and the art of housekeeping, if the word "*home*" is to remain current in the Canadian vocabulary, and this most important phase of our national life is to keep abreast of commercial and industrial progress.

AGRICULTURE

In agriculture we have many problems which are of tremendous importance and interest. The fascination of studies which may lead to the growth of two stalks of wheat where one grew before, of a head which has a double number of grains of the same size, or the same number of grains of double size or a strain which improves quality without impairing quantity, or is adapted to land which was formerly unprofitable or useless, can not fail to arouse

national and even international interest since it concerns the food supply of the world. Such studies as those which resulted in the production of the Marquis wheat in Canada, or the work of Hayes in Minnesota wheats, or of Zavitz of Guelph on barleys, have meant millions upon millions of dollars to the new world and food for the nations. The expeditions to Asia of Hensen, of South Dakota, in the search for, and development of, alfalfa suited to cold winters and dry summers brought about an economic revolution and furnished a story as fascinating as is to be found in literature. Babcock and Russell have added millions annually to Wisconsin's assets through their contributions to the making of cheese, butter and other milk staples.

However, these are only a few of the rural problems where scientific, patient work, and wide propaganda are needed. Humanity is traveling cityward and the best of our peoples must have their faces turned again to the country, if we are not to suffer disaster. This means that rural life must be made possible. It must become a life and cease to be an existence. Toward this end every influence in our provinces and in our land must be brought to bear, but it is quite as much a social as an economic question. It includes cultural and artistic phases quite as much as scientific agriculture and the food supply. It also must not lose sight of rural hygiene.

In our land we have many problems which relate indirectly to the soil, and we realize at once that we must develop agriculture as a profession comparable in all respects to other professions. For this work, undoubtedly, we must also develop an artisan class with industrial training just as we must take pains to foster the teaching of other trades and callings.

It is to be hoped that all our universi-

ties will bring every influence to bear to establish anew the dignity of labor. It must be confessed at the present time that Canadians, like Americans, are abandoning manual work as fast as they can to newcomers from Europe and Asia. Either the creation of a peasant class must be squarely faced at this time or the dignity and the vital need of labor must be duly impressed on Canada's native sons. We must return to the ways of our fathers. We must all work if we would be strong, and we must be strong if we would work.

FORESTRY AND FOREST ENGINEERING

The need for the study of forestry and of horticulture is becoming better recognized. Wisconsin has a forest-products laboratory built by the federal government and maintained by the state university, in which such problems as those which are now engaging the attention of the Fifth National Conservation Congress are studied. Every one interested in agriculture needs to know about shelter belts, the care of fruit trees and kindred subjects. Not only for forestry in relation to agriculture but for forest engineers there is an increasing demand. In such countries as British Columbia, the provincial government needs them for the proper conservation and intelligent use of its forest resources, and the Dominion government for its large timber holdings, whilst the transcontinental railways have in their possession vast forest tracts.

The important corporations whose operations are extensive in lumbering industries will need men who are trained in botany, animal biology, chemistry, physics, mathematics, engineering, economics and commerce, in order that they may fulfil those functions which they may reasonably be called upon to perform.

ENGINEERING, ARCHITECTURE, MINING AND COMMERCE

In Canada pioneering has spelled engineering. We lay out and build roads and railroads, construct bridges, tunnel mountains, discover, measure and harness water powers, prospect for and produce from mines, and in every way possible explore and develop our country, realizing at the same time that as yet we have not well begun. We have to develop our resources and facilities for our own use and also in order that we may exchange our commodities with other nations. Chemistry, physics and biology have all to be utilized in our manufacturing processes in increasing degree. Our people have to be housed and so have our industries, we and our products have to be transported. We must fetch to and carry from other nations. Naval architecture and building must be improved even yet. Markets and marketing require most careful investigation and report. Business needs to be put on the plane of a profession and in our universities, pulpits and forums, only one brand of ethics need be taught. The golden rule brought down to date will serve this and many other generations.

For all these activities we must busy ourselves in training men. Our universities need no longer argue the question of whether college men can "make good" in the practical walks of life. The people want more of them. That is why they are providing the provincial and state university with departments, schools and colleges to develop these branches.

LAW

Pioneering is the struggle with nature, the fight with things, the adjustment of the rest of the world to man. As soon as we arrive at the stage when we touch elbows—begin to be "civilized" forsooth—we have

need of the lawyer to help us adjust man's rights to mankind's needs. We do wisely if we train these men carefully who are to compose our difficulties, lest they only stir up strife where they should be strenuous for peace. We expect them to be the leading force in developing society by making the individual conform to the mass. They must therefore be men of the highest integrity and trained most broadly. They need a knowledge of what has gone before. They need all the cultural training available and they most certainly need some information in regard to the sciences if they are to be intelligent in the making and interpretation of laws which are intended to crystallize our most advanced thought and fix common procedure.

The preceptor system is ideal when the student is article to one who can and will teach and who feels at once his opportunity and his obligation. It is, however, as unreliable as it is antiquated, and is antiquated because it is unreliable. It belongs to the dark ages when public schools and compulsory education were unknown. Whilst medicine has taken many liberties with pedagogical principles, she has long ago given up the apprentice system, and of recent years has introduced modern teaching methods into her schools. Law must inevitably follow. The public will doubtless develop state mechanisms for training our lawyers, who have meant and must continue to mean so much to British progress and national stability. British law is the pride of the empire.

MEDICINE AND ALLIED BRANCHES

The people realize in increasing degree that the provision of better physicians and nurses for their children is the best possible public investment, a form of life insurance that is safer than any other. They understand that it is the people's business

to provide adequate training and to insist that those who are to be entrusted with the lives and welfare of our citizens avail themselves of that training and present satisfactory evidence of proper qualification for their work. Medicine is being increasingly socialized. We are drifting perceptibly nearer to the time when the doctor will be a public servant and not a member of a privileged class. It is therefore only just and right that he be trained at public expense. This means provision not only of biological, chemical and physical laboratories, but laboratories of medical science, clinical laboratories, hospitals, dental infirmaries, dispensaries, nurses' homes, and other such facilities, all as a part of the equipment of a provincial university.

The expense of such an undertaking should properly be assessed not alone against the university, however. It is a good public investment when the by-product more than pays the total cost of operation. The teaching hospital, the backbone of such a university school of medicine, by returning to the community from which the patient comes a self-supporting and independent citizen in lieu of a helpless being—a burden to himself and others—is far more than paying the cost of maintenance. In fact, the cost of operating the hospital and its associated laboratories should really be charged not to education, but to public works, not to life insurance for our children, which medical teaching means, but to current provincial business, which increases the earnings of to-day. We are learning to know that in fairness both to the sick who can not work, and to the well who must work, the place for the sick is in the hospital. The sick can not receive such kind and efficient care at home whilst the amateur nursing and household disturbance both interfere with the work and reduce the vitality of the well.

PUBLIC HEALTH AND SANITATION

To provide for medicine is not to meet the needs of public health. Its conservation involves phases of medicine, engineering, law-making and enforcement, sociology, economics, education and many other lines of endeavor. The construction of the Panama Canal, that marvel of engineering, has been possible only because at length man has been able to stay the hand of the grim destroyer. The annual death toll under the De Lesseps regime was one out of each ten. It is now less than one out of each hundred amongst the white employees in the canal zone.

The same forces of nature which science has tamed for man's use and pleasure, the biological and physical sciences, have been applied in the war with disease. Death can be postponed and man's working period lengthened. Man was in sad need of improved weapons for his own defense in view of the rapid multiplication of complexities developed by modern life which masses thousands together in a few minutes and as quickly disperses them. *Velocitania*—speed craze—is the microbe's friend, whilst our high tension life gives him the needed hold by increasing vital waste. In turn, hygienic success and extension of man's active period means increased population and adds new problems to the many perplexities of the engineer, the architect, the sociologist, the economist and the statesman. And so we are mutually helpful and mutually harmful.

We have come to recognize that the individual's fitness is not only his prime business but the public's affair as well. In increasing degree are we interfering with personal liberty for the benefit of the race. In line with this tendency we must undoubtedly expect to see colleges and schools of public health, as differentiated from medical schools, developed in our state uni-

versities. They can only succeed by enlisting all official and volunteer public health agencies in the training of workers for the many fields in which specialists are required. They involve so much of basic science and culture that they can be developed only in universities and will be most successful in state or provincial or federal universities. The members of the teaching corps are already available if we add the trained workers in official and voluntary public health services, who can furnish the practical work which in the language of the medical school might be termed "public health clinics."

It is time that all those who are charged with responsibility for the care of the public health be trained before they undertake that responsibility rather than to receive their training at the expense of the public welfare. This the public realizes and will demand.

PEDAGOGY

With the advance in professional and industrial education has come a very real need for teachers' colleges which can not be met by our normal school system. Their proper home is in our universities since they require on their staffs the very men there available. They must be taught to know and then to teach. We must teach teachers of domestic science the mechanic arts, agriculture, nursing, personal hygiene and many other lines of work. These embryo teachers must have their practise schools to learn under proper direction the art of teaching. A nice articulation must be made, however, in order to see that in our educational system there is neither uncovered ground nor undue overlap. The need of training drilled public servants available for permanent positions in a stable profession is so overwhelming that there is little present danger of overlap.

THE NEED FOR TRAINING PROFESSIONAL
COORDINATORS

Life is a continual fight with physical, biological and social environment. In the struggle man has gradually acquired a composite equipment. As in the process of evolution from single celled organisms to the higher animals there is loss of cell versatility and acquirement of very special function on the part of cells, cell groups and systems, so in the social organism development has come about. We have come far and are going farther towards specialization. Our increase in aggregate knowledge has come by this very specialization, yet whilst this gives each of us more power in his own sphere it makes him increasingly dependent upon others. The more knowledge we acquire in our own field, the less we are apt to have in our neighbor's. Inevitably we shall become incapacitated from over-specialization unless we develop our "*social nervous system*" to a corresponding degree. Our problems become more largely governmental. We need professional coordinators; we require those who can comprehend and compel cooperation. We have come to the point in our development when we must have trained statesmen, publicists, journalists, social experts, public hygienists, lawmakers, and last, but not by any means least, spiritual advisers and leaders. As man gets to know more about himself and his environment, and learns to control in increasing degree the forces of this world, he does not lose interest in the question of whence he came and whither he goes. He needs to be understood and helped whilst here, however. We begin to see more clearly the relation between disease and morality, between poverty and crime and between poverty and sickness. We know that physical efficiency is inexplicably interwoven with mental and moral vigor. We

appreciate better each day the unrighteousness of ignorance and of disease, as well as of doing less than one's best.

LITERATURE, THE ARTS AND SCIENCES

Mention of these has been reserved till now because of the obviousness of their place in any scheme of university development. At no very recent date they largely constituted the college and university curricula, with the exception of science, which has only become respectable in Cambridge within a generation and is now being tolerated in Oxford. We can not so well develop agriculture and other industrial activities which involve science and culture independently of them, since their ramifications interdigitate with and involve all our social and economic functions. These interrelations are so self-evident that no argument is needed in support of the claim for increase in efficiency and the decrease in effort and expense which result from a policy which coordinates these branches and provides a system of vital checks and balances. Home management, agriculture, forestry, engineering, architecture, mining, manufacturing and commerce, medicine, law, public health and all such practical workaday phases of our national life are rooted in the arts and sciences. They presuppose the culture of the humanities, a familiarity with the fine arts, a foundation in the life and literature of the past, a knowledge of current events in this and other lands and the possession of linguistic and other such tools. They are the more practical application of biological, physical and social sciences to the betterment of man in order to place him *en rapport* with his environment and adapt his environment to his requirement as well as to adjust the rights and obligation of man to the needs of mankind and the will of his Creator.

To divorce literature, science and the

arts from the crafts, the industries and the professions is unthinkable. The dreamer needs the doer, the artist needs the artisan, the poet needs the planner, the scholar needs the statesman. The man with the telescopic eye, who sees so clearly the things of to-morrow, but trips over the threshold of to-day, needs the social myopic whose condition results from too close and too prolonged contact with the minute work of the world. One warns the other of things to come whilst he in turn is protected against the dim dangers of the day. The so-called practical men need theory, and the theorists need practise. The workers need uplift and the apostles of culture need contact with the earth. The people's university must meet *all* the needs of *all* the people. We must therefore proceed with care to the erection of those workshops where we may design and fashion the tools needed in the building of a nation and from which we can survey and lay out paths of enlightenment, tunnel the mountains of ignorance and bridge the chasms of incompetence. Here we will generate currents of progress and patriotism while we prepare plans and begin the construction of a finer and better social fabric than the world has known. Having done our best to found provincial universities without provincialism, let us pray that posterity may say of us that we builded even better than we knew.

It's the olden lure, the golden lure, it's the lure of the timeless things.

F. F. WESBROOK

THE UNIVERSITY OF BRITISH COLUMBIA

November 19, 1913

THE INDIAN LADDER RESERVATION

GEOLOGISTS in many parts of the world will be interested in the announcement recently made of the gift to the state of New York as a public park of the "Indian Ladder" and its

adjoining portions of the Helderberg mountains escarpment in Albany county, New York. Next, perhaps, to the Schoharie Valley, the Helderbergs and the Indian Ladder have the most intimate and ancient association with the history of geology in this state and are really a classic ground in American geological science. Interesting not alone for its geology, as the original section of the "Helderberg formation" and its various subdivisions, with their profusion of organic remains, the Indian Ladder is equally commanding as a scenic feature. There is perhaps nothing just like it in origin and effectiveness. From the summit of the long sheer limestone cliff the eye commands the panorama of the conjoined Hudson and Mohawk Valleys picturesquely spread out over a vast area bounded at the north by the foothills of the Adirondacks and at the northeast by the Taconic mountains and the Berkshires. And over this splendid picture generations of geologists have gazed, for the Helderbergs have been the Mecca of geologists for well nigh a century.

The generous gift to the people of New York State comes from Mrs. Emma Treadwell Thacher, widow of the late Hon. John Boyd Thacher, a distinguished statesman, historian and litterateur. Its more than 350 acres extends along the escarpment so far as to include all its most striking portions and the new reservation is essentially a geologic and scenic park. It was the intention of Mr. Thacher that it should have this ultimate disposition. Mr. Thacher, who had a summer home in the Helderbergs, was much in Europe engaged in his historical researches. On one of his returns he told me that he had heard so much of the Helderbergs, their rocks and their fossils, among circles of savants with whom he was thrown that he determined to do his part to preserve this famous cliff from any danger of invasion, because of its natural beauty and extraordinary scientific interest. Impressed by the worth of preserving such natural monuments, Mr. Thacher's high-minded purpose has now been made effective.

JOHN M. CLARKE

NEW YORK STATE MUSEUM

*THE OHIO STATE BOARD OF HEALTH AND
THE OHIO STATE UNIVERSITY*

THE first move in the general plan to increase the cooperation of the State Board of Health and the Ohio State University has been to move the offices of the former to Page Hall on the university campus. The laboratories are still located at the Hartman building but as soon as the botany building is vacated and remodeling completed, the laboratories will also be moved to the university. It is the intention of Dr. E. F. McCampbell, secretary and executive officer of the State Board of Health, to increase the facilities for popular education and for the education of health officers along public health lines. The educational facilities possessed by the university will be of great value in furthering this plan.

Dr. R. G. Paterson, formerly secretary of the Ohio Society for the Prevention of Tuberculosis, is now in charge of the division of tuberculosis and public health education in the State Board of Health and it is intended to make use of the university in furthering the work of this division. While it is true that the university will be of value to the State Board of Health, the latter will also be of value to the university.

Dr. Frank G. Boudreau, director of the division of communicable diseases, plans to place at the disposal of qualified medical students the facilities which his division possesses in the investigations and research work carried on by his department.

The secretary, Dr. E. F. McCampbell, who is also director of the hygienic laboratories, plans to begin the manufacture of vaccines and anti-toxins as soon as the laboratories are established at the university. This will be done in connection with the university laboratories and the veterinary department. The public health exhibit of the State Board of Health is now at Coshocton and will show at Uhrichville, East Liverpool, Bellaire, and other points in the northeastern portion of the state in the next two weeks. The exhibit was very successful at Newark and Zanesville and drew large numbers of sightseers daily. A lecture on public health is given each evening by

one of the members of the staff of the State Board of Health. This lecture is illustrated with stereopticon slides and is followed by moving picture films on various subjects. The exhibit comprises photos, aphorisms, cartoons and models illustrating the prevention of tuberculosis, occupational diseases, communicable diseases and various phases of sanitary engineering work and other matters pertaining to sanitation. Improvements and new material have been constantly added to the exhibit and it has been modified in accordance with the effect produced upon various communities. The exhibit was shown before the Columbus Academy of Medicine and the conference of the State Board of Health with city health officers in January, 1914.

SCIENTIFIC NOTES AND NEWS

THE committee of the Lister memorial fund has commissioned Sir Thomas Brock, R.A., to execute a medallion portrait of the late Lord Lister, to be placed in Westminster Abbey.

SIR J. J. THOMSON has been elected president of the Physical Society of London.

PROFESSOR ERNST HAECKEL was ennobled on the occasion of his eightieth birthday.

DR. SIMON SCHWENDENER, professor of botany at Berlin, has celebrated his eighty-sixth birthday.

SURGEON-GENERAL GORGAS, on his return from his mission to South Africa, and his two companions, Dr. Darling and Major Noble, will be entertained at a complimentary dinner in London on March 23. The chair will be taken by Sir Thomas Barlow, president of the Royal College of Physicians, who will be supported by Sir Rickman Godlee, president of the Royal College of Surgeons; Sir Francis H. Champneys, president of the Royal Society of Medicine; Sir David Ferrier, president of the Medical Society of London; Sir Havelock Charles, president of the Society of Tropical Medicine and Hygiene; by the regius professors of medicine in Oxford and Cambridge, and by the directors of the medical services of the Royal Army and Navy.

WE learn from the *Journal* of the American Medical Association that the Robert Koch Foundation at Berlin for Research on Tuberculosis has granted a subsidy of \$500 to Professor Lexer, of Jena, for research on the action of light rays on tuberculosis tissue, and to Professor Kayserling, of Berlin, to carry on his roentgenologic investigation of the distribution and extent of infection in tuberculosis-ridden families.

THE National Institute of Social Sciences presented gold medals of the Institute to Dr. Abraham Jacobi and Professor Henry Fairfield Osborn at the New York Academy of Medicine on March 20.

THE Council of the Royal Astronomical Society has elected to honorary membership Miss Annie Cannon, of the staff of Harvard College Observatory.

DR. BARTON WARREN EVERMANN has resigned the position of chief of the Alaska Fisheries Service, United States Bureau of Fisheries, and that of curator, division of fishes, United States National Museum, and has accepted the directorship of the museum of the California Academy of Sciences.

DR. RAYMOND FOSS BACON has been appointed to succeed the late Dr. Duncan as director of the Mellon Institute for Industrial Research of the University of Pittsburgh. He was formerly associate director of the institute.

LIEUT.-COL. CHARLES F. MASON has been appointed chief health officer of the Canal Zone, and Lieut.-Col. George D. Deshon superintendent of the Ancon Hospital.

PROFESSOR C. E.-A. WINSLOW, of the New York City College and the American Museum of Natural History, has been appointed advisory expert on public health education by the New York State Commission of Health.

DR. PHILIP ADOLPH KOBER has resigned as research chemist in the Harriman Research Laboratory of the Roosevelt Hospital, his resignation to take effect at the end of September.

PROFESSOR LÖHNIS, of the laboratory for agricultural bacteriology in the University of

Leipzig, has accepted a call to a position in the Department of Agriculture at Washington.

MR. J. ADAMS, assistant in botany in the Royal College of Science, Dublin, has been appointed to a position under the Canadian government.

DR. HANS VON STAFF, docent for geology at Berlin, has been appointed geologist for German Southwest Africa.

At the recent meeting in Chicago of the Association of Medical Colleges, officers were elected as follows: *President*, Dr. Isadore Dyer, Tulane University; *Vice-president*, Dr. Charles R. Bardeen, University of Wisconsin; *Secretary-treasurer*, Dr. Fred. C. Zapffe, 3431 Lexington Street, Chicago; *Members Executive Council*, Dr. William J. Means, chairman, Ohio State University; Dr. Randolph Winslow, University of Maryland; Dr. Egbert Le Fevre, University and Bellevue Hospital Medical College; Dr. F. C. Waite, Western Reserve University, and Dr. E. P. Lyon, University of Minnesota.

DR. DAVID STARR JORDAN has sailed from Italy for Australia, where he is giving a series of lectures. He will visit Ceylon, where he will make a collection of fishes and later expects to make a study of the results of the war in the Balkan States. He plans to reach California late in August.

PRESIDENT HARRY PRATT JUDSON, of the University of Chicago, will go to China under the auspices of the Rockefeller Foundation of New York to examine and report on the situation there in regard to medicine, surgery and public health. The party will include also a medical expert. They will sail from New York on March 21, proceeding to Paris and thence to Moscow, arriving at Peking on April 19. President Judson will visit the principal places in China where work of the character in question is carried on. During the heat of the summer President and Mrs. Judson expect to spend some time in Japan, and early in the autumn they may go to southern China, sailing from Hongkong for San Francisco and stopping at Honolulu on the way. The investigations in China will occupy six months.

PROFESSOR D. C. MILLER, of the Case School of Applied Sciences, has given two lectures on sound at Cornell University. The first lecture, on "The Science of Musical Sounds," was given under the auspices of the College of Arts and Sciences; the second, on "The Physical Characteristics of Vowels," under the auspices of the Sigma Xi Society.

THE Washington Academy of Sciences held a joint meeting with the Chemical Society of Washington on March 16, when an address on "The Chemistry of Colloids" was given by Dr. Wolfgang Ostwald, of the University of Leipzig.

BEFORE the Geographic Society of Chicago on March 13 a lecture was given by Professor Henry J. Cox, in charge of the Chicago office of the United States Weather Bureau, on "Cranberry Bogs and the Cranberry Industry."

DR. W. W. CROSBY, Baltimore, delivered a lecture on February 28, before the students in highway engineering, Columbia University, on the subject of "Cost Data in Highway Engineering."

IN connection with an arrangement of exchange lectures with the Missouri School of Mines, the University of Kansas, the Iowa State College and the University of Wisconsin, Professor H. H. Stoek, of the department of mining engineering of the University of Illinois, has returned from giving a course of three lectures at Rolla, Missouri, Lawrence, Kansas and Ames, Iowa. The subjects of the lectures were the "Geography, Geology and Properties of Anthracite"; the "Mining and Preparation of Anthracite," and the "Sociological Features of the Anthracite Industry."

UNDER the auspices of the State Water Survey of the University of Illinois, the sixth annual meeting of the Illinois Water Supply Association held a three day's session March 9 to 11 in Urbana. Among the university men giving addresses were Director Edward Bartow, of the State Water Survey; Professor A. M. Talbot; Professor Otto Rahn and Dr. John A. Fairley. The latter spoke on "Public Control of Water Supplies in Illinois." Among

the speakers from a distance were Mr. E. M. Chamot, of Cornell University; Mr. Wm. M. Booth, of Syracuse, N. Y.; Mr. Jay Craven, of Indianapolis; Mr. W. M. Cobleigh, of Montana State College, and Dr. A. J. McLaughlin, of Washington, D. C.

DR. EDWARD SINGLETON HOLDEN, astronomer and librarian of the United States Naval Academy, formerly director of the Lick Observatory, died on March 15, aged sixty-eight years.

SIR JOHN MURRAY, the eminent Scottish naturalist and oceanographer, was instantly killed in an automobile accident on March 16. He was born in Canada in 1841.

MR. GEORGE WESTINGHOUSE, the distinguished inventor and engineer, died on March 12, aged sixty-eight years.

DR. THOMAS MORGAN ROTCH, professor of pediatrics in the Harvard Medical School and well known for his publications on the diseases of children, died on March 9, aged sixty-five years.

MISS EDITH ETHEL BARNARD, Ph.D., instructor in chemistry at the University of Chicago, died on March 8.

DR. F. KORTE, a well-known physician of Berlin and father of the distinguished surgeon, has died at the age of ninety-six years.

THE death is also announced of Dr. August Pauly, associate professor of zoology at Munich.

THE U. S. Civil Service Commission announces an examination for assistant explosives engineer, on April 8, 1914, to fill a vacancy in this position in the Bureau of Mines, at Pittsburgh, Pa., or at other places in the field, at salaries ranging from \$1,620 to \$2,100 a year, and also for an assistant drainage engineer, for both irrigated lands and humid regions, in the Office of Experiment Stations, Department of Agriculture, at salaries ranging from \$1,000 to \$1,500.

WE learn from *Nature* that by the will of the late Alderman H. Harrison, Blackburn, legacies amounting to £82,600 are bequeathed to public objects, among which are: £1,000 each to the Imperial Cancer Research Fund,

the Cancer Investigation Department of the Middlesex Hospital, and the Cancer Hospital for cancer investigation; £5,000 to Manchester University for general purposes, and £1,000 for the Chinese chair; £2,000 to Blackburn Grammar School for playfields, and £1,000 for university scholarships.

ABOUT thirty pictures of psychologists have been secured and reproduced for distribution by Professor E. A. Kirkpatrick, of Fitchburg, Mass., in accordance with the plan outlined in this journal some months ago.

ARRANGEMENTS are in progress for a Meteorological Congress to be held in Venice in September and to which meteorologists of all countries are to be invited.

THE Pasteur Institute of Paris has invited directors of similar institutes and antirabic services throughout the world to a conference on hydrophobia with special reference to etiology, prophylaxis, treatment and statistics. The conference will meet in the Pasteur Institute April 7 to 10, 1915.

Nature reports that the London School of Tropical Medicine has sent an expedition to China to study the mode of dissemination of human diseases caused by trematode parasites, especially bilharziosis, and the relation of such diseases to those occurring in domestic animals. Investigations into ankylostomiasis will also be carried on. The members of the expedition are Dr. R. T. Leiper, helminthologist of the Tropical School; Surgeon E. L. Atkinson, R.N., and Mr. Cherry-Garrard. The two last named were members of Scott's Antarctic Expedition, and the name of Surgeon Atkinson is familiar to the public as the leader of the search party which recovered the bodies of Capt. Scott and his companions.

UNIVERSITY AND EDUCATIONAL NEWS

AN anonymous gift of \$20,000 has been made to the library of Haverford College. The interest is to be used for the purchase of books on literature, history and art.

At the meeting of the Council on Medical Education of the American Medical Associa-

tion, held in Chicago on February 24, the following colleges were given higher ratings: The University of Pittsburgh, School of Medicine; Jefferson Medical College, and the Starling-Ohio Medical College (now the College of Medicine of the Ohio State University) were raised from Class A to Class A+. The Atlanta Medical College, Atlanta, Ga., and the Fordham University School of Medicine, New York City, were raised from Class B to Class A.

At the regular meeting of the board of trustees of the University of Pennsylvania held March 9, it was decided that beginning with the session 1914-1915, all candidates for the degree doctor of public hygiene shall be required to have had identically the same preliminary education as that now demanded of those entering upon medical courses leading to the degree, doctor of medicine; that is to say, at least two years of college work plus the specified amount of physics, chemistry and biology as set forth in the University of Pennsylvania catalogue.

At Columbia University the following assistant professors have been promoted to the grade of associate professor, from July 1, 1914: Charles P. Berkey (geology); Bergen Davis (physics), and James H. McGregor (zoology). Instructors promoted to be assistant professors are as follows: Jean Broadhurst (biology—Teachers College); Clifford D. Carpenter (chemistry—Teachers College); Harold B. Keyes (physical education—Teachers College); Arthur C. Neish (chemistry); John M. Nelson (chemistry); Edward D. Thurston, Jr. (mechanical engineering); Harold W. Webb (physics); Mary T. Whitley (educational psychology—Teachers College), and Jesse F. Williams (physical education—Teachers College).

WILLIAM J. MILLER, PH.D., professor of geology for the past nine years at Hamilton College, has been elected professor of geology at Smith College.

MR. J. M. WORDIE has been appointed demonstrator of petrology at the University of Cambridge.

DR. OTTO KLEMM, docent at Leipzig, has been appointed professor of psychology in Alberta University, Edmonton, Canada.

DR. KARL HESCHELER has been appointed professor of zoology and anatomy at Zurich, to succeed Professor A. Lang, who retires from active service.

PROFESSOR ALBERT BUSHNELL HART has been selected by the German government as Harvard exchange professor at the University of Berlin for the academic year 1914-15.

DISCUSSION AND CORRESPONDENCE

THE RELATIVE IMPORTANCE OF SULPHATES AND PHOSPHATES IN SOILS

It has been demonstrated by a number of investigators¹ that the total sulphur content of soils is generally low, the amount usually not exceeding 1,000 pounds in an acre surface foot. Further, it has been shown that an equal mass of soil will contain quite as much and very often a greater quantity of phosphorus. Another fact of equal importance and which has been abundantly demonstrated is that the demands for sulphur by farm crops is not appreciably less than for phosphorus.

No one familiar with this subject would question the necessity of maintaining the supply of phosphorus in a soil, but only lately has attention been focused on the sulphur problem, placing that element in the same category with phosphorus as an element of low supply and an economic factor in crop production and permanent fertility.

On the basis of "total" analysis it appears certain that the amount of sulphur in our common soils is not larger than the phosphorus supply, and, further, that the amount brought to the surface annually in the rainfall will not compensate for the loss the land sustains by drainage.

Yet when we admit these facts we have only opened the problem of the necessity of sulphur

fertilization. It is becoming rather common practise to attach a great deal of importance to the total quantity of any given essential plant food element in the soil, believing that this alone will measure or determine the permanent crop-yielding power of a given soil. For a measure of permanent crop production and for the knowledge upon which to build the soil to a certain plane of efficiency these determinations undoubtedly have value, but in the problem of continued fertilization too often we lose sight of the influence of the added material on the biological soil processes and the physiological balance of nutrients essential for the optimum growth of plants.

While it is admitted that the soil supply of sulphur is as low as the phosphorus supply, yet the question must be raised and answered—will sulphates influence crop production to the same extent as added phosphates?

It is apparent that part of the soil sulphur is in organic forms and part as sulphates, but that the organic forms are constantly being oxidized to sulphates. The additional fact that drainage waters are richer in sulphates than in phosphates must lead to the conclusion that the solubility of the sulphates in the soil water is much greater than the solubility of the phosphates. This being true, it is apparent that a lesser total quantity of sulphates in a soil would be as efficient in maintaining a sufficient sulphate concentration in the feeding zone of the plant as a much greater total quantity of phosphates.

In addition to the question of solubilities the important factor of the relative effects of sulphates and phosphates on the biochemical soil processes must be raised. Such important biochemical processes as ammonification, nitrification, nitrogen fixation, and the rate of decomposition of organic matter with its accompanying liberation of carbon dioxide can not be too greatly emphasized in deciding on the relative fertility of soils.

It has been demonstrated beyond question in certain phases of fermentology that cellular and enzymatic activities are markedly increased by the presence of soluble phosphates. Harden and Young have shown that the ac-

¹ Bogdanoff, Abstract Expt. Station Rec., 11, 723; Dymond, Hughes and Dupe, Jr. *Agr. Sci.*, 1905, 1-107; Hart and Peterson, Research Bull. No. 14, Wis. Exp. Station; Shedd, Bull. No. 174, Ky. Agr. Expt. Station.

tivity of the yeast cell or its zymase is greatly accelerated by the presence of these substances. The question then may properly be asked whether soluble phosphates do or do not accelerate the activity of the organisms or the enzymes responsible for those important soil processes mentioned above, and further whether sulphates effect in the same degree such accelerations.

Work in this and other laboratories has progressed far enough to indicate that soluble phosphates have a very material effect in increasing the number and consequently the rate of ammonification, nitrification, nitrogen fixation, and carbon dioxide output of those soil organisms capable of carrying out these processes, while sulphates do not, at least in the same degree, accelerate their multiplication. My thanks are due Professor C. Hoffmann for conducting such experiments.

From such results it is evident that sulphates will not be of the same importance in increasing crop production as can be expected from the phosphates. An adequate supply of sulphates is, of course, necessary, and for those crops making an abundant use of sulphur, such as the high protein plants and the members of the Cruciferae, a further concentration in sulphates of the soil water may often result in increased crop production. But to the phosphates must be ascribed functions additional to that of merely maintaining a certain concentration of phosphorus in the soil solution—namely, the important function of greatly accelerating the biological activities of the soil.

In conclusion, however, it should be emphasized that as crop production per unit of area increases through the extended use of added phosphorus and attention to proper soil reaction, there will result an increased demand for sulphur.

UNIVERSITY OF WISCONSIN

GRIZZLY BEARS: SKULLS WANTED

HALF a century ago a considerable number of wholly distinct species of grizzly bears inhabited the western part of North America. They ranged from the eastern edge of the

Great Plains in Manitoba and the Dakotas westerly to the Pacific coast in British Columbia and California, and from the shores of the Arctic ocean south into Mexico. The species inhabiting Alaska and the western provinces of Canada, though reduced in numbers, may still be counted among the living, but those of the western United States are with few exceptions extinct; and what is still worse, in most cases only a few skulls remain to afford future students a fragmentary and imperfect picture of the great carnivores which not long ago were dominant figures in our wild life.

For twenty-three years I have been engaged in a study of the bears, and have been favored with specimens (mainly skulls) from nearly all the museums and private collections of the United States and Canada. Still, owing to wide gaps in this material, many questions have arisen which can not be answered. Not only is it impossible to map the ranges of the different species with anything like precision, but in some cases, owing to the absence of skulls of adult males, the characters which serve to distinguish one species from another can be determined only in part.

Therefore, in the hope of obtaining more light on some of these questions before going to press, I wish to make a final appeal to all who have skulls of grizzlies in their possession. I am anxious to see as many skulls as possible of both sexes from all parts of the western United States, British Columbia, Alberta, Manitoba, Yukon Territory and Alaska, and would like to purchase or borrow all that I have not already seen. Owners of skulls will confer a favor by addressing

QUOTATIONS

THE PARTICIPATION OF UNIVERSITY PROFESSORS
IN POLITICS¹

My dear President McVey: I regret to advise you that I find myself out of harmony

¹ Correspondence between the professor of law and the president of the University of North Dakota.

with the university administration on the question of academic freedom, which I regard as fundamental; and I therefore tender my resignation as professor of law, to become effective at the end of the present academic year, that is to say, in June, 1914.

When I joined the faculty here a year ago last September, it never occurred to me that restraints would be imposed upon my freedom of action in public affairs. Indeed, it was represented that public life presented an attractive avenue to the professor in North Dakota.

Last year I made several speeches during the presidential campaign and induced two of my colleagues to do likewise. After the election, much to my surprise and chagrin, you objected to what we had done. In the interview that you granted my associates and myself, you first took the position that members of the faculty must not take part in national and state politics, although they might participate in municipal politics. I suggested that my resignation was ready, if you spoke advisedly. You asked me not to resign. The interview was terminated with the understanding that you personally were opposed to professors having anything to do with politics, except municipal, but left it to each man to determine his own course.

In October of the present year, at the request of the local leaders, I attended a statewide Progressive conference at Fargo. The gathering was informal, not open to the public, and for purpose of organization. A few days after the meeting, I was advised by the dean of the law school that you had told him that Judge Young, one of the university trustees, had objected to my participation in the conference, taking the position that members of the faculty must keep out of politics, on penalty of dismissal. I was further informed that his position represented the policy of the administration and this has since been confirmed.

It scarcely is necessary for me to observe that I regard such a policy unjust to the faculty and the institution; and I am satisfied that a professor could not legally be removed for exercising the prerogative of citizenship.

Under the circumstances, if I were to remain here, I should be compelled either to engage in an unseemly and distasteful wrangle with the administration or to sacrifice the rights and be recreant to the duties of citizenship. Neither course commends itself to me.

In my humble judgment, it will be a sorry day for American education, if the policy of suppression adopted here ever becomes general. One can not, it seems to me, reach his full development, either as a teacher, a citizen or a man, unless he retains normal relations with life. Without this a university professor, no matter how strong his intellect or profound his learning, must become—like the image of Nebuchadnezzar—possessed of a gold head, but feet of clay.

As a last word, may I say that my disposition toward you personally is cordial, and I do not hold you responsible for the policy with which I take issue so squarely. I respect your scholarship and your talent as an administrator, and trust that our relations may remain friendly. All of which is respectfully submitted.

Sincerely yours,

JOSEPH L. LEWINSOHN

My dear Professor Lewinsohn: I have your letter in which you indicate your intention of resigning at the end of the year. I shall present the resignation to the board of trustees at their next meeting for their action. I respect your point of view, though I do not agree with it, and wish you to understand that there is no personal feeling in the matter, so far as I am concerned, and that our relations will remain cordial.

I wish, however, to say that in my opinion you are wrong. We have been insisting for some time the judges of the court shall remain out of politics and have put them upon non-partisan tickets, and it is no longer good form for a judge to take the stump in a political election. To my mind, a professor in a state university occupies much the same position, with even more emphasis upon the necessity of his remaining in a judicial position than in the case of a judge of the state court. I do not want my boy taught political economy, for instance, with a Democratic or Republican

bias, and just as soon as I enter politics I begin to act as a partisan and I lose my place as a judge and an unbiased individual. As soon as a professor enters politics he makes the university an object of political purpose. This is so for the reason that the political activity may be utilized and places gained through political control.

As politics go, you can not escape their consequences, and to develop a theory about academic freedom that you can escape them, and still take part in them, is entirely beside the mark. There is no restriction placed upon the teaching of a professor, or upon his speaking upon social and economic questions, but as soon as he allies himself with a political body which seeks to control the political power of the state, there is danger. The life of the universities in this state and elsewhere depends upon their being able to keep above this kind of politics, the kind that you want to engage in. Professor Ross, of the University of Wisconsin, put it in this way: "We (meaning professors) ought to be willing to give over the forum to the politicians for a period of six weeks, when we have it all the rest of the year."

I do not acquiesce at all in your view that the educational life of the universities and of the state is endangered by this attitude. To my mind, it is good sense and good policy.

With best wishes for your success, I remain,

Yours very truly,

FRANK L. McVEY,

President

SCIENTIFIC BOOKS

Objektive Psychologie. By W. VON BECHTEREW. Authorized translation. Leipzig and Berlin: Teubner. 1913. Pp. viii + 468. 16 Mks. unbound, 18 Mks. bound.

The study of animal behavior is developing a tendency among certain psychologists to emphasize motor expression as a research method in human psychology. Professor Max Meyer's "Laws of Human Behavior" is typical of this trend, though it shows the influence of traditional psychology in many respects. Other American writers are leaning

in the same direction, and Professor J. B. Watson has recently thrown down the gauntlet by proclaiming boldly that behavior is the one fruitful method of psychological investigation, and that the study of consciousness is unscientific and barren.

In his "Objective Psychology" Professor Bechterew attempts a systematic development of psychology according to the behavior method. He does not expressly reject introspective psychology, but proposes to eliminate it from the present work. Starting with the concept of the neuropsychic reflex he aims to describe the whole mental life of man in terms of expression, discarding entirely conscious phenomena, such as sensation, feeling and thought. He calls this science objective psychology or psychoreflexology. A better English equivalent is behaviorism or behavior psychology. Considering the newness of the field, Bechterew's attempt is fairly successful. He has outlined systematically and with remarkable completeness the various aspects of human mental life as they are manifested in every sort of objective expression.

A distinction is made at the outset between purely nervous processes and neuropsychic processes. The former depend solely on present stimuli and inherited nervous mechanisms; the latter are modified by past individual experience (pp. 16, 22, 24). Every impression "leaves in the nerve centers a certain trace which under certain circumstances can be re-experienced and thereupon appears as an associative or psychic reflex" (105). Impressions or stimuli are classed as external (that is; from peripheral sense organs) and internal (organic, etc.); the resulting expressions are either movements, vasomotor activity, or secretion (164). Responses to external stimuli are termed reflexes, those due to internal stimulation are called automatic movements (165), though the distinction is not always sharply marked (166).

Reactions of every type have become organized into complex "acts" by means of special nervous mechanisms aided by the traces of former impressions. Thus an external stimulus may give rise to a complex act such as

walking, through the association of a series of movements whose stimuli have previously accompanied the same stimulus (180). In the formation of such associations inhibition plays an important rôle. Bechterew defines instinct as a complex movement or act which follows *internal* stimulation and results in satisfying some organic need or protecting the organism from harmful or disturbing influences (188). In contrast with instinct, imitation and the circular reflex are based on associations which modify the responses to *external* stimuli.

The complex reflexes which involve association find expression in all three motor modes (movement, vasomotor activity and secretion) and may be investigated in several ways. The author prefers his own method, that of motor association reflexes, to Pawlow's salivary method (262). Considerable space is devoted to an analysis of emotional expression, which he calls mimicry. Bechterew holds that these reflexes have more than a phylogenetic value; they perform an important function in the given reaction itself (327).

The last part of the book examines three specialized forms of complex response, the concentration reflex, symbolic reflex and personal reflex. The concentration reflex is the behavior analogue of attention, and one has no difficulty in identifying the symbolic reflex with language. The discussion of vocal language is thorough, but the treatment of gesture and writing is disappointingly brief. One is surprised that the analysis of sensation and perception, or rather sensory and discriminatory responses, is taken up in connection with symbolic reflexes. It is true that sensation as such can not be brought into the behavior psychology. It can only be investigated by means of responses on the part of an observed organism; and the quantitative measure of sensation in man according to our classic laboratory methods usually involves verbal reactions. Nevertheless this holding back of the discussion of elementary phenomena in a systematic treatise will strike most psychologists as a defect in the objective method itself. It is but fair, however, to point out that the

introspective psychology of our fathers relegated elementary *motor* phenomena to the footman's seat in much the same way.

The analysis of personality from an objective standpoint will arouse special interest and is likely to become the focus of criticism. Bechterew holds that "the personal sphere represents the totality of traces from organic associative reflexes, around which a part of the reflexes aroused by external stimuli group themselves by association" (431). These organic traces are experienced in connection with every change of general bodily condition; their sum total forms the "inner kernel of the Neuropsyché" (432).

"Personal reactions are termed *acts* and *deeds*" (435). They are distinguished from other reactions, not by the character of the external stimuli, but by the relation of the present stimuli to the individual's past history. The hunter is aroused to action by the flight of a game bird, which is quite unnoticed by the man with no sporting proclivities. The same stimulus may even affect the same individual differently at different times. Personality in this objective sense guides all our lower activities. Concentration (attention) and the selection of association traces are thus in part determined internally; this is Bechterew's substitute for the free-will experience of subjective psychology. Of interest is his application of muscular work and fatigue to the investigation of personality. Believing that muscular fatigue is due to impairment of both muscle and nerve centers, Bechterew considers that the ergographic curve furnishes a measure of individual efficiency. It is to be regretted that the analysis of personality is not so detailed as the rest of the work.

Bechterew's book is the most consistent attempt at a thorough-going objective psychology so far made. It may be questioned, however, whether he has succeeded in banishing subjective psychology altogether from his pages. In many places affective and emotional terms are used to characterize the basis of reaction. This is especially noticeable in his analysis of hedonic states (107-123), internal reflexes (171-175), and emotional expression

(278 ff.). To be sure these terms are usually set off in quotation marks like the pseudonyms of notorious criminals. In many cases it is only fair to interpret them as a shorthand symbol for a physiological condition. But it does not seem legitimate to distinguish between various sorts of reaction on the basis of subjective conceptions (such as joy and sadness, p. 60, anxiety, dissatisfaction, etc., p. 111) unless some clear physiological differentia of these hedonic states have first been determined. This the author often neglects to do. He gives physiological *descriptions* rather than physiological *definitions* of these terms; even when he substitutes the terms *sthenic* and *asthenic* for pleasure and pain his criterion is apparently subjective. It is scarcely fair to repudiate subjective psychology, and at the same time to employ subjective hedonic data to differentiate between various modes of reaction.

The book needs considerable condensation. Too much space is devoted to details of particular laboratory experiments, which could be summed up in a few sentences with proper references. The German translation is satisfactory except in the transliteration of proper names from the Russian alphabet. The names of several well-known writers are inexcusably misspelled; for example, Dadge (for Dodge), Fallerton (Fullerton), Merrillier (Mariller), Burdon (Bourdon) and Hawding (Höfding). In one place the values of the time threshold are given in seconds instead of thousandths (422).

It is clearly too soon to attempt an estimate of such a new departure from beaten paths as this work affords. The contemporary "subjective" psychologist of whatever type is not yet sufficiently grounded in behaviorism to evaluate its merits. But however critical of the objective standpoint the reader may be, he will find Bechterew's book worth a very careful study.

HOWARD C. WARREN

PRINCETON UNIVERSITY

The Fisheries of the Province of Quebec.

Part 1. Historical Introduction. By E. T. D. CHAMBERS. (Published by the Depart-

ment of Colonization, Mines and Fisheries of the Province of Quebec.)

To any one interested in the history of Canada and the historical development of what was its first and long its chief industry (and would be still were it not for the demand of the newspapers on the Canadian forests), Mr. Chambers's work is fascinating. The author has brought together, from whatever source and with infinite pains, abundant excerpts from ancient relations, with ancient illustrations and contemporary portraiture bearing upon the historic pursuit of the cod and its confreres in the Quebec waters. The golden cod on the Boston State House emblazons a fact that is easily and rather wittingly forgotten: that the *Mayflower* colonists and their successors came to that rock-bound coast to worship God in their own way; but "So God have my soul," said the High and Mighty Prince James, when the Leyden agents of the Puritans told him they were to go to "Virginia" for the *fishing*, "'tis an honest trade; 'twas the Apostles' own calling." So they came to fish for cod as well as to worship in their chosen way, while the sturdy Bretons and Normans who had reached the Quebec coast long years before came simply to fish for cod.

There is romance of history in the Quebec fishing, for it is "more than four hundred years since Basque and Breton fishermen gathered the first harvest of the sea from the waters that wash the coasts of Labrador and Gaspé." Cartier, penetrating the straits of Belleisle into the Gulf in 1534, met a Norman fisher; and after his day, as soon as the wealth of the new French waters became known at home, the men of St. Malo, Honfleur and the Biscayan ports flocked to these shores in great numbers. Even after the conquest the Quebec fishing remained French; while the fishing masters came out from the Channel islands and their descendants to-day still control the industry.

In giving the descriptive records of ancient procedures, Mr. Chambers has assembled a really large part of the active industrial history of maritime Quebec during its romantic

period, for history was in the making in these turbulent waters and along these sequestered shores long before the Gloucesterman was conceived. The purpose of this notice is not to direct attention to the scientific analysis of the fishing business, into which it does not purport to enter, but to applaud the worth and fitness of this contribution to the historic development of the oldest known industry on the North American continent and to congratulate the author on the attractive manner in which he has presented his subject. As an official document it bears the cachet of dignity and the assurance of durability.

JOHN M. CLARKE

NOTES ON METEOROLOGY AND CLIMATOLOGY

CLIMATOLOGY AT THE ASSOCIATION OF AMERICAN GEOGRAPHERS

At the tenth annual meeting of the Association of American Geographers at Princeton, N. J., January 1 and 2, 1914, six climatological papers were presented:

The Weather Element in American Climates:

R. DE C. WARD.

Since American climates are chiefly made of cyclonic weather, this factor is all-important; the actual conditions affect us and not the averages. Winter is a cyclonically-controlled period—at this time of year practically the whole country is covered with cyclonic paths. In summer, solar control is uppermost, the cyclone paths are in the north and the cyclones weak. Thus cyclone paths migrate with the sun. As the distribution of meteorological elements in a cyclone is different in different parts of the country, Professor Ward is preparing regional cyclonic weather types for the United States.

The Frostless Period in Maryland and Delaware: OLIVER L. FASSIG.

The number of days (average of 20 years) between the last severe frost or freezing temperature in the spring and the first in the fall ranges from 130 days in the west to over 200 days in the immediate vicinity of Chesapeake Bay. For further study of plant growth as related to climatic conditions, phenological

observations of similar plants in the same soil (transported) are to be undertaken at many points, each group being visited every 10 or 15 days.

Storm Frequency in the United States and Europe: C. J. KULLMER.

A geographical study of cyclone frequency of the United States 1874 to 1891 and of Europe 1876 to 1891 shows irregular or perhaps periodic latitude variations of cyclone frequency. An attempt was made to correlate these latitudinal changes with the eleven-year periodical latitude change of sun-spot belts. Such changes of cyclone frequency are probably accompanied by rainfall and temperature variations.

The Pleionian Variations of Temperature:

HENRY ARCTOWSKI.

Swings of temperature covering a year or more seem to be the result of periodic fluctuations in the solar constant plus variations caused by volcanic dust in the atmosphere. This coincides with the results obtained by Abbot and Fowle and many others.

Climate and Human Efficiency: ELLSWORTH HUNTINGTON.

From a study of the piece-work wages of 270 operatives in some Connecticut factories, 1910-1912, it was found that their maximum efficiency came in December with a secondary maximum in May. The minimum of about 85 per cent. of the maximum came in January and another of about 90 per cent. in August. Highest efficiency usually occurred with out-of-door temperatures near 58° (F.), and with wide variations of temperature from one day to the next. Other meteorological elements considered individually in this connection gave no satisfactory results. Further work will be done to compare mental efficiency with weather.

The Snowfall About the Great Lakes: CHARLES F. BROOKS.

The snowfall in this region is heavy because of much moisture precipitated at low temperatures by the many winter cyclones. On account of the cooling action of land on the prevailing west winds blowing across the lakes, the east shores get more snow than the

west. Ice on the lakes by diminishing evaporation reduces the snowfall of the leeward shores. Thus the heaviest snowfall comes early in winter on the east shores in marked contrast with the late winter maximum on the west shores.

THERMOMETER EXPOSURE

DR. W. KÖPPEN in the *Meteorologische Zeitschrift*, October and November, 1913,¹ has presented the results of a long study of thermometer exposure in different parts of the world with many shelters. His results are briefly stated below. To determine air temperature the thermometer must be sheltered from radiation but not from the air; the air must not travel far between radiators before reaching the thermometer, and the shelter must have low specific heat and be a poor conductor. The English (Stevenson) shelter in the small form of 1883 fulfills the above stipulations very well. But to eliminate the effect of heating by the sun and excessive cooling at night, a screen is necessary. Dr. Köppen proposes a small and simple screen of grass, rushes, brush or palm leaves to be set over the shelter in such a way as to exclude sunlight when the sun is more than 20 degrees above the horizon. The roof of the shelter should be of this material also. As the small Stevenson shelter is too small for the ordinary thermograph and hygrograph, a combined instrument is suggested instead. Since the English shelter is extensively used, these modifications proposed by Dr. Köppen to obtain strictly comparable temperature data can be made with facility.

CHANGES OF CLIMATE

PROFESSOR J. W. GREGORY, of Great Britain, presented a paper entitled "Is the Earth Drying Up?" before the Royal Geographical Society, December 8, 1913.² Of the three

¹ "Einheitliche Thermometeraufstellung für meteorologische Stationen zur Bestimmung der Lufttemperatur und Luftfeuchtigkeit," pp. 474-487, 513-523, 1 plate.

² Review by "E. G.," *Nature*, London, December 11, 1913, p. 435.

general views in this matter, the first (Prince Kropotkin) maintains that the earth has a general tendency towards drought; the second (Professor Ellsworth Huntington) that while there is this general drying the more important changes are pulsatory, and the third (Mr. R. Thirlmere) that climate varies in cycles of 2,000 years or more and that we are now cooling. Professor Gregory put the evidence from different countries on a map. The result shows probable desiccation in historic times in Central Asia, Arabia, Mexico and South America; but increased rainfall in the United States of America, Greenland, Sweden, Roumania and Nigeria. There seems to have been no appreciable change in Palestine, North Africa, China, Australia and by the Caspian Sea. Thus while there seem to have been local variations there has been probably no general change in climate in the historic past. At any rate, no great universal change could be expected without a considerable change in land and water distribution or of the intensity of solar radiation.

AIR MOVEMENT IN THE CIRRUS LEVEL

THE geophysical institute of the University of Leipzig has recently issued a work by Th. Hesselberg, "Die Luftbewegungen im Cirrus-niveau."³ From comparison of the tracks of cyclones and anticyclones with the stream lines shown from cirrus observations, the following results have been obtained. Cyclones and moving anticyclones move in the same directions as the air in the cirrus level over the center. The velocity of movement of cyclones and anticyclones is in the mean 0.2 to 0.4 of the velocity of air in the cirrus level. The relative velocity is smaller the deeper the minimum and the higher the maximum.

Air movement in the cirrus level seems to be controlled by the pressure and temperature conditions on the earth. The more intense the cyclone or anticyclone and the smaller the horizontal temperature gradient the greater is its effect on the currents above. The disturbance which a cyclone makes on the cirrus path

³ Second Series, Vol. 2, 73 pp., 48 maps, Leipzig, 1913.

works back onto the track of the cyclone. Thus a cyclone may have loops in its path.

JOURNAL OF THE SCOTTISH METEOROLOGICAL SOCIETY

THE annual volume (Vol. XVI., 3d Series, XXX.) of this society including rainfall returns and meteorology of Scotland for 1912 has recently appeared. There are seven special articles. Agricultural meteorology is touched in three—Dr. W. N. Shaw, "On Seasons and Crops in the East of England" (pp. 179-183), A. Watt, "On the Correlation of Weather and Crops in the East of Scotland" (pp. 184-187), and Dr. H. N. J. Miller, "The Composition of Rain Water Collected in the Hebrides and in Iceland, with Special Reference to the Amount of Nitrogen as Ammonia and as Nitrates" (pp. 141-158). Dr. Shaw has another article, "Upper Air Calculus and the British Soundings during the International Week (May 5-10, 1913)" (pp. 167-178). The other papers are—M. M'C. Fairgrieve, "A Possible Two-hourly Period in the Diurnal Variation of the Barometer" (pp. 158-166), Dr. E. M. Wedderburn, "On the Appearance of the Surface of Fresh-water Lochs in Calm Weather" (pp. 189-193), and Dr. G. A. Carse, "Note on Atmospheric Electric Potential Results at Edinburgh during 1912" (pp. 188-189).

NOTES

ON January 1, 1914, the United States Weather Bureau began to issue daily weather maps of the Northern Hemisphere with pressures indicated in millibars and temperatures in Absolute Centigrade degrees. This map is printed on the back of the usual Washington weather map of the United States.

THE Central Meteorological Bureau of France has created a special forecast service for aeronauts.

MR. R. C. MOSSMAN, of the Argentine Weather Service, is acting editor of *Symons's Meteorological Magazine* and director of the British Rainfall Association during the temporary absence of Dr. H. R. Mill on account of ill-health.

THE Italian Meteorological Society will hold an international congress in Venice in September, 1914. The higher atmosphere, climatology, aerology, meteorology and maritime meteorology will receive particular attention.

IN connection with studies of air currents, pilot balloons are used extensively in Germany. Vertical currents are determined by comparing the observed rate of ascent of the balloons with the theoretical. The turbulent meeting planes of opposing vertical currents are usually marked by clouds.⁴

THE daily synchronous weather charts of the southern part of the Southern Hemisphere, October 1, 1901, to March 31, 1904, compiled from the observations of ships and the numerous Antarctic expeditions give the first extensive (though general) information concerning the cyclones of the south temperate and sub-antarctic zones. The paths of these cyclones lie far south, particularly in summer, when they are beyond latitude 60 degrees. The average rate of progression is about 20 kilometers per hour—about the same as ocean cyclones elsewhere.⁵

CHARLES F. BROOKS

HARVARD UNIVERSITY

SPECIAL ARTICLES

THE SYSTEMATIC POSITION OF THE ORGANISM OF THE COMMON POTATO SCAB

SCAB is probably the most widely distributed disease of the potato tuber. We are indebted to Professor Roland Thaxter for associating a specific organism with the cause of this disease. His description of the morphological and biological characters of this organism are so careful and his substantiation of the same as causal agent, so conclusive, that we are unable to add anything of material importance—at any rate here—from our own study of the organism.

Professor Thaxter named the organism *Oospora scabies*¹ by which "provisional"

¹ Dr. A. Peppeler, *Deutsche Luftfahrer Zeitschrift*, November 26, 1913, pp. 578-580.

⁵ See *Nature*, London, December 4, 1913, pp. 393-395.

name the disease organism has since been known. "Provisional" because Thaxter himself expresses his doubt as to the correctness of referring the organism to the genus *Oospora*, remarking that the genus *Oospora* as given by Saccardo has no scientific value.

We had occasion to carefully study this organism recently, and from our observations desire to rectify the nomenclature.

From Saccardo's interpretation of the genus *Oospora*, and from its numerous species, we must consider it as a fungus pure and simple, a hyphomycete of the Mucidinæ-Amerosporæ. The organism of potato scab proves not to be a fungus. It differs in morphological characters considerably from what is our present conception of an *Oospora*. Mr. G. C. Cunningham at the meeting of the American Association for the Advancement of Science in Washington, D. C. (1911), expressed his opinion that the potato-scab organism belongs to the "higher bacteria" and he proposes to place it in the genus *Streptothrix*. We are also inclined to regard it as a Schizomycete of the filamentous kind, belonging to the Chlamydo bacteriaceæ. On endeavoring to place the organism in its proper genus, we found ourselves confronted by one of the most perplexing problems of botanical nomenclature, which promises a rich harvest to those who are fond of such study.

At first we considered *Streptothrix* Cohn² the correct genus, but found later that Corda³ in 1839 founded this genus for another hyphomycetous fungus of which *S. fusca* was his species. Hence, according to the Vienna rules, this name was no longer available for another plant genus. Saccardo still considers this name as given by Corda valid, including four species all of which are distinct from our organism. Furthermore, *Streptothrix*, as erroneously used by Cohn, possesses no "sheaths," whereas our organism does, however delicate they may appear.

Other names such as *Cladothrix*, *Nocardia* and *Actinomyces* have also been loosely used for members closely related to the organism of potato scab. *Cladothrix* is out of the question owing to its false branching and ciliate spores.

Actinomyces was established by Harz in 1878⁴ and his description undoubtedly shows generic relationship to our organism. Harz describes *A. bovis* as causing "lump jaw" or actinomycosis.

Homer Wright, M.D.,⁵ pleads in favor of the name *Actinomyces* for use only in connection with the organism causing actinomycosis, and suggests that all other organisms of this genus should be known as *Nocardia* "because the use of the generic term *Actinomyces* for them logically leads to giving the name actinomycosis to those cases of suppurative processes due to infection with certain members of the group." This point of view is opposed to even the most elementary conception of botanical nomenclature.

Now *Nocardia* is the name at present in use by Saccardo for members of our group of organisms.⁶ It was established by Trevisan in 1889; "he considered the generic name *Actinomyces* untenable because the generic name *Actinomyce* (without the terminal 's') was given by Meyen in 1827 to a fungus (*Hydrotremellina* (Carus)) described by him ('*Actinomyce Horkelii*')."⁷ According to Article 57 of the International Rules of Vienna, it is distinctly laid down that two generic names, even though differing by one letter only, are to be regarded as distinct, which applies in this case.

Hence *Nocardia* Trev. is untenable and *Actinomyces* Harz must stand for these organisms. The organism of potato scab properly belongs to this genus; in consequence I feel justified in correcting the nomenclature as follows:

¹ Ann. Rep. Conn. Exp. Station for 1891, p. 153.

² *Beiträge zur Biol. d. Pflanzen*, Heft 3, pp. 186 and 202.

⁶ Saccardo, "Sylloge, etc." VIII., p. 927.

⁷ *Linnaea*, Vol. 2, pp. 433.

Actinomyces scabies (Thaxter) Guessow =
Oospora scabies, Thaxter.

At the same time I shall rectify the genus and species as far as given by Saccardo under *Nocardia* as follows:

Actinomyces Harz 1878 = *Streptothrix* Cohn 1875; Rossi Doria 1891 = *Bacterium Afanasiev* 1888 = *Oospora Sauvageau et Radis* 1892; Thaxter 1891 = *Discomyces Rivolta* 1878; R. Blanchard 1900 = *Nocardia de Toni et Trevisan* 1889; R. Blanchard 1900 = *Actinomyces Gasperini* 1894 = *Actinomyces Meyen* 1827 = *Cladothrix Macé* 1897.

Actinomyces farcinica (Trev.) Guessow =
Nocardia farcinica Trev.

Actinomyces bovis (Harz) Guessow = *Nocardia Actinomyces* Trev.

Actinomyces Foersteri (Cohn) Guessow =
Nocardia Foersteri (Cohn) Trev.

Actinomyces arborescens (Edingt.) Guessow =
Nocardia arborescens (Edingt.) Trev.

Actinomyces ferruginea (Trev.) Guessow =
Nocardia ferruginea Trev.

DIVISION OF BOTANY,
EXPERIMENTAL FARMS,
OTTAWA, CANADA

THE AMERICAN SOCIETY OF ZOOLOGISTS

THE Central and Eastern Branches of The American Society of Zoologists met in joint session at the University of Pennsylvania, Philadelphia, December 29, 1913, to January 1, 1914, inclusive, in conjunction with The American Society of Naturalists, The American Society of Anatomists and the Federation of American Societies for Experimental Biology.

At the meeting for business, held during the afternoon of December 30, the following persons were elected to membership in the society:

CENTRAL BRANCH

James Edward Ackert, Kansas State Agricultural College, Manhattan, Kan.

Robert Chambers, University of Cincinnati, Cincinnati, Ohio.

John Morton Elrod, Missoula, Montana.

E. H. Harper, Northwestern University, Evanston, Ill.

Frederick Isely, Central College, Fayette, Mo.

Ruth Marshall, Rockford College, Rockford, Ill.

H. L. Wieman, University of Cincinnati, Cincinnati, Ohio.

EASTERN BRANCH

Gardiner C. Bassett, Carnegie Station for Experimental Evolution, Long Island, N. Y.

Raymond Binford, Guilford College, North Carolina.

Maynie R. Curtis, Agricultural Experiment Station, Orono, Me.

Hubert Dana Goodale, Amherst College, Amherst, Mass.

B. H. Grave, Knox College, Galesburg, Ill.

Emily Ray Gregory, Buchtel College, Akron, Ohio.

Louise Hoyt Gregory, Barnard College, New York.

George Lester Kite, Wistar Institute, Philadelphia.

C. C. Little, Harvard College, Cambridge, Mass.

E. Carlton McDowell, Yale University, New Haven, Conn.

Norman Eugene McIndoo, Bureau of Entomology, Washington.

Edith M. Patch, University of Maine, Orono, Me.

Alice Robertson, Wellesley College, Wellesley, Mass.

The "committee on organization and policy," appointed at the meeting held at Princeton in 1911, submitted its report in the form of a new constitution, the text of which had been printed and distributed to all members of the society several days prior to the meeting. This proposed constitution was considered section by section and, with certain amendments, was unanimously adopted. In its adopted form, it is as follows:

THE AMERICAN SOCIETY OF ZOOLOGISTS' CONSTITUTION

Article I

Name and Object

Sec. 1. The society shall be called the American Society of Zoologists.

Sec. 2. The object of the society shall be the association of workers in the field of zoology for the presentation and discussion of new or important facts and problems in that science and for the adoption of such measures as shall tend to the advancement of zoological investigation in this country.

Article II

Membership

Sec. 1. Members of the society shall be elected from persons who are active workers in the field of zoology and who have contributed to the advancement of that science.

Sec. 2. Election to membership in the society shall be upon recommendation of the executive committee.

Sec. 3. Each member shall pay to the treasurer an annual assessment as determined by the society. This assessment shall be considered due at the annual meeting and the name of any member two years in arrears for annual assessments shall be erased from the list of members of the society; and no such persons shall be restored to membership unless his arrearages shall have been paid or he shall have been reelected.

Article III

Officers

Sec. 1. The officers of the society shall be a president, a vice-president, a secretary-treasurer, and the members at large of the executive committee.

Sec. 2. The executive committee shall consist of the president, the vice-president, the secretary-treasurer and five members elected from the society at large. Of these five members, one shall be elected each year to serve five years. If any member at large shall be elected to any other office, a member at large shall be elected at once to serve out the remainder of his term.

Sec. 3. These officers shall be elected by ballot at the annual meeting of the society, and their official terms shall commence with the close of the annual meeting, except that the secretary-treasurer shall be elected triennially and shall serve for three years.

Sec. 4. The officers named in section 1 shall discharge the duties usually assigned to their respective officers.

Sec. 5. Vacancies in the board of officers, occurring from any cause, may be filled by election by ballot at any meeting of the society. A vacancy in the secretary-treasurership occurring in the interval of the meetings of the society may be filled by appointment until the next annual meeting by the executive committee.

Sec. 6. At the annual meeting the president shall name a nominating committee of three members. This committee shall make its nominations to the secretary not less than one month before the next annual meeting. It shall be the duty of the secretary to mail the list of nominations to all members of the society at least two weeks before the annual meeting. Additional nominations for any office may be made in writing to the secretary by any five members at any time previous to balloting.

Article IV

Meetings of the Society

Sec. 1. Unless previously determined by the society the time and place of the annual meeting of the society shall be determined by its executive committee. Special meetings may be called and arranged for by the executive committee. Notices of such meetings shall be mailed to all members of the society at least two weeks before the date set for the meeting.

Sec. 2. Sections of the society may be organized in any locality by not less than ten members, for the purpose of holding meetings for the presentation of scientific papers. Such sections shall have the right to elect their own officers and also associate members; provided, however, that associate membership in any section shall not confer membership in the society.

Article V

Quorum

Twenty five members shall constitute a quorum of the society, and four a quorum of its executive committee.

Article VI

Changes in the Constitution

Amendments to this constitution may be adopted at any meeting of the society by a two thirds vote of the members present, upon the following conditions:

(a) The proposed amendment must be in writing and signed by at least five members of the society.

(b) This signed proposal must be in the hands of the secretary at least one month before the meeting of the society at which it is to be considered.

(c) The secretary shall mail copies of the proposed amendment to the members of the society at least two weeks before the meeting.

By-laws

A set of by-laws, for the guidance of officers of the society in the performance of their duties, was also adopted in substance, but the work of embodying the same in appropriate and clear phraseology was delegated to the executive committee.

Officers of the society for the year 1914, as provided by the new constitution, were elected as follows:

President—C. E. McClung, University of Pennsylvania.

Vice-president—M. F. Guyer, University of Wisconsin.

Secretary-treasurer—Caswell Grave, Johns Hopkins University.

Additional Members, Executive Committee—To serve one year, H. E. Jordan, University of Virginia; to serve two years, H. F. Nachtrieb, University of Minnesota; to serve three years, H. V. Wilson, University of North Carolina; to serve four years, George Lefevre, University of Missouri; to serve five years, A. F. Shull, University of Michigan.

The treasurers of the Central and Eastern branches made financial statements, which were examined and found correct by an auditing committee consisting of Harold S. Colton and Wm. A. Kepner. These reports showed a total balance in current funds, December 30, 1913, of \$597.22.

The custodian of the permanent fund, J. H. Gerould, reported the receipt of a 15 per cent. dividend on the claim of the society against the Industrial Savings and Loan Company of New York.

A finance committee consisting of Frank R. Lillie, chairman, Caswell Grave and E. G. Conklin, was created to have charge of the investment of the permanent fund and the executive committee was instructed to add to the permanent fund from current funds of the society whenever such action is deemed expedient.

A committee consisting of Henry B. Ward, chairman, G. H. Parker and C. E. McClung was appointed to confer with a committee of three from the American Society of Anatomists on the subject of premedical education.

The "Mathews Plan for the Organization of an American Biological Society" was referred to the executive committee for consideration and report to a future meeting.

The committee of delegates, on which the American Society of Zoologists was represented by G. H. Parker, recommended that the secretaries of the American Society of Zoologists and other affiliated societies consult with the secretary of the American Society of Naturalists as to the place of future meetings. This recommendation was approved by unanimous vote.

The recommendation of the executive committee that a list of members, and the new constitution and by-laws of the society be published this year by the secretary was also approved.

At meetings held on December 29, 30 and January 1, the following papers were read either in full or by title:

COMPARATIVE ANATOMY

The Intestinal Epithelium of Trematodes: HENRY S. PRATT.

A Contribution to the Evolution of the Cestode, Rostellum: FRANKLIN D. BARKER. (Illustrated with lantern slides.)

Barker and Adson have recently described a new genus and species of Cestode, *Proteorostellum sphaerulum* from the intestine of softshell turtles.

This form differs from the other known genera of the *Proteocephalidae* in having a well-defined apical organ on the head or scolex. Other morphological and histological differences also distinguish this form.

In order to arrive at the correct interpretation of this organ a careful comparative study of the various apical structures found in cestodes was made.

The comparative study shows that the apical organ of this new cestode from the turtle is neither end-organ, terminal sucker nor muscle-cone. The rostellum of different cestodes vary greatly in their structural complexity so that several distinct grades may be recognized. Comparisons with these rostellum clearly shows that the apical organ of the turtle cestode is a rostellum of a very simple type.

It seems then that we have in this rostellum the simplest and most primitive type of cestode rostellum yet described and one which possibly represents the prototype from which the more complex types have evolved. A well-defined series of rostellum, developing in complexity, can be established, beginning with this very simple type found in the turtle cestode.

On the basis of this series of cestode rostellum we would define the cestode rostellum as an organ varying in size, shape and complexity; having a definite individual musculature, intrinsic, extrinsic or both; more or less retractile; armed or unarmed; situated on the apex and equidistant from the acetabula of the cestode scolex. A more detailed discussion of this question will appear in a paper soon to be published from this laboratory by Geo. M. Covey on "The Microscopic Anatomy of *Proteorostellum sphaerulum* Barker and Adson."

Further Notes on the Embryonic Skull of Eumeces:

EDWARD L. RICE.

A. Secondary Tympanic Membrane.—Gaupp emphasizes the contrast in position of the secondary tympanic membrane of the mammals and the physiologically similar membrane stretched between the rim of the fenestra cochleæ and the lateral margin of the basal plate in *Lacerta*. Observations on *Eumeces* largely bridge this gap and indicate a real homology not recognized by Gaupp. Early stages agree with *Lacerta*; in later embryos the membrane is clearly a part of the wall of the otic capsule.

B. Exit of Glossopharyngeal Nerve.—The above interpretation helps to harmonize the seemingly contradictory data concerning the course of the ninth nerve in the reptiles, described as "Extra-capsular" in *Lacerta*, *Hatteria* and the *Crocodylia*, and as "intra-capsular" in *Chelone*, *Eruys* and *Tropidonotus*. The cause in both cases may be interpreted as intra-capsular, the penetration of cartilage or connective tissue depending on the relative extent of these tissues in this part of the otic capsule, i. e., upon the size of the fenestra cochleæ. Observations on *Eumeces* confirm this view. Some specimens agree fully with *Lacerta*; in others the nerve clearly penetrates the cartilage of the median walls of the capsule, although no lateral penetration of the cartilage has been observed. These variations are not correlated with age.

Observations on Sympathetic Ganglion Cells: F.

W. CARPENTER.

The Vascular System of the Florida Alligator: A. M. REESE.

The Morphology of the Pectoral Spine and Gland in Certain Catfishes: H. D. REED. (With demonstration.)

The Innervation of the Integument of Chiroptera: J. E. ACKERT. (With lantern slides.) (Introduced by Robert K. Nabours.)

The integument of *Myotis lucifugus* (LeConte) and *M. subulatus* (Say), stained *intra vitam* with methylene blue, reveals a number of nervous structures. Among them are free nerve terminations which can be seen most readily in the flying and interfemoral membranes, and which, so far as the writer has been able to ascertain, have not been reported heretofore in these organs.

Nerves end on pelage hairs at three levels and in three different sheaths of the follicles. These endings are: (1) a superficial nerve ring situated ectad of the orifices of the sebaceous glands, and giving off nerve threads in the connective tissue sheath; (2) fine, varicose or flattened nerve fibrils lying immediately entad of the openings of the sebaceous glands, and terminating on the hyaline membrane parallel to the long axis of the hair; (3) nerve fibrils at the level of the lower third of the follicle, usually taking a horizontal position in the outer root sheath. Apparently, nerve endings similar to the last type have not been described previously in the hair of the bat.

The skin contains two kinds of special sensory end-organs: (1) a small, elongate *end-bulb* into which a single medullated nerve fiber enters, extends approximately to the opposite end, and terminates in a slight enlargement; (2) a large, round, cellular *terminal corpuscle* innervated by a single fiber which disappears among the cells of the organ. Terminal varicosities are abundant in the region of the hairs outside of the follicles.

In the skin of the face, especially, there are well-developed striated muscles which bear motor end-plates. While some of these plates appear to be beneath the sarcolemma in the integument, they are unquestionably so placed in the muscles of the tongue.

Of interest are the large, modified sweat glands, some of which have numerous fibrils running about them. In the absence of definite observations on the innervation of sudoriparous glands, it seems possible that these fibrils, which resemble sympathetic post-ganglionic neurites, may form plexuses about the glands similar to intracapsular plexuses around cell bodies of sympathetic neurones.

Blinded bats when on the wing probably perceive

obstacles through the sense of touch by the effect of condensations of the atmosphere (produced on approaching the object) upon the free nerve terminations in the epidermis and the superficial nerve rings of the hair follicles.

EMBRYOLOGY

On the Parallelism Between Increase in Permeability and Abnormal Development of Fish Eggs: J. F. McCLENDON.

The morphology of abnormal *Fundulus* embryos has been studied by Dr. Stockard. My work has been merely an attempt to find the cause of the abnormalities.

I found that distilled or sea-water solutions of nicotine and the salts of Na, Li, K, Ca and Mg all produced the same abnormalities in the embryos. In other words, any one of the above substances produced all of the types of abnormalities when applied to eggs in early cleavage stages.

If the eggs are placed in distilled water or "balanced" salt solutions no salts diffuse out of them. Only the kations have to be balanced; for example, if eggs are placed in a solution containing nitrates of Na, K, Ca and Mg, no chlorides diffuse out of them.

But if the eggs are placed in distilled-water solutions of any one of these substances, the salts contained in the eggs diffuse out into the solutions and may be detected by ordinary chemical analysis. It is thus shown that solutions which cause abnormalities also increase the permeability of the eggs to salts (and perhaps to other substances).

Solutions that were too weak or had acted for too short a time to produce abnormalities, had increased the permeability of the eggs to a slight degree. Therefore, the increase in permeability seems to be the cause and not an effect of the abnormal development.

The Effect of X-rays on the Rate of Cell Division in the Early Cleavage of Planorbis: A. RICHARDS.

An Experimental Study of Concrecence in the Embryo of Cryptobranchus alleganiensis: BERTRAM G. SMITH. (Illustrated with lantern slides.)

By the method of vital staining the following facts concerning the formation of the embryo of *Cryptobranchus* were established: (1) A band of cells occupying the lateral and ventral parts of the equatorial region of the late blastula, during gastrulation comes to occupy the corresponding parts of the margin of the yolk plug, and converges on

the site of the closing blastopore. (2) During gastrulation there is a confluence of material lying in the region of the dorsal lip of the blastopore; in connection with the process of overgrowth and in turning of the dorsal lip of the blastopore this material shifts from either side toward the median line. (3) The movement of the neural folds is a movement of translation, not a wave movement. The neural folds include material originally situated at least 90 degrees apart, which is thus brought into apposition in the median line.

The bearing of these facts on the theory of concrescence will be discussed when the paper is published in full.

The Behavior of the Skeletons in Experimentally Fused Larvæ: A. J. GOLDFARB.

On the Behavior of Sea-urchin Embryos When Incorporated in Sea-urchin Lymph Plasmodia: H. V. WILSON.

Segmenting eggs included in lymph plasmodia, eventually in wound membranes, continued to develop for a time. Many reached through radial elongation of the blastula cells and subsequent delamination a solid (sterroblastula) stage, after which the cells became dissociated, lying scattered or in amorphous masses in the midst of the general plasmodium. A large amount of the embryonic tissue underwent degeneration. On the other hand, groups of small dissociated blastomere cells established connection with one another and the general lymph plasmodium through the development of protoplasmic processes. They thus went so far as to become a part of the syncytium which constitutes the regenerative tissue. Their further fate could not be traced, and the evidence as to their permanency is thus negative.

In some of the experiments a considerable number of segmenting eggs remained adherent to the surface of the plasmodium. The development of these was near the normal. About the time when the cells acquire cilia, instances of fusion between the blastulae were common. While the further development of these giant blastulae was not followed, it would seem that the combination of lymph plasmodium and giant embryos is something essentially like the "syrphoplasmic" masses described by Janssens (1904).

A Pair of Tracheal Invaginations on the Second Maxillary Segment of the Embryo of the Honey Bee: J. A. NELSON.

At a period shortly after the completion of the germ layers, and contemporaneous with the appearance of the rudiments of the appendages and

of the stomodæum, a pair of tracheal invaginations appears on each of the ten segments caudad of (but not including) the prothoracic segment. These invaginations by branching give rise to the tracheal system. At the same time a pair of invaginations appears on each side of the second maxillary segment. These occupy a position on this segment similar to those of the tracheal invaginations of the trunk segments, and are also similar to them in size and general appearance. Each of the tracheal invaginations of the second maxillary segment is directed somewhat caudad, and develops with great rapidity into a sac with four diverticula and a constricted external opening. One of the diverticula is directed caudad, one dorsal and the other two cephalad.

The external opening of the tracheal invagination now closes completely, the branched sac thus formed being cut off completely from the hypodermis. The caudad diverticulum of the sac now extends further caudad to meet and unite with the cephalad diverticulum from the tracheal invagination of the second thoracic segment. The dorsal diverticulum extends toward the dorsal mid line, where it meets and fuses with the corresponding diverticulum of the opposite side, forming the anterior tracheal loop or commissure of the main tracheal trunks. The two cephalad diverticula form tracheal branches supplying the brain and the muscles of the cephalic appendages. The tracheal invaginations on the second maxillary segment, therefore, produce a portion of the anterior end of each of the main tracheal trunks, in addition to the tracheæ found in the head.

Tracheal invaginations were described by Hatschek in 1877 in the gnathal segments of a lepidopterous larva. Examination of Hatschek's figures show that these invaginations were those forming the tentorium and mandibular apodemes, and they have generally been so regarded. Tracheal invaginations have not since been described in the head of any insect embryo.

Further Studies on the Development of the Cranial Sympathetic Ganglia in Vertebrates: ALBERT KUNTZ.

*The Early Cleavage of *Cirratus Grandis*, Verrill: JOHN W. SCOTT. (Illustrated with lantern slides.)*

In common with most annelids the cleavage is unequal. It differs from other marine annelids in that cleavage becomes very irregular after the 8-celled stage. The egg is further characterized by the peculiar and important behavior of the yolk

lobe. The egg shows a high degree of organization at an early stage. Whatever may be the significance of the yolk lobe, it is an adaptation associated with early cleavage, apparently correlated with the karyokinetic figure; it aids in producing unequal cleavage; it isolates cell materials, so that they are unaffected by early transformations of the nucleus; and, in *Cirratus*, it appears to aid in the arrangement of the cell pattern. Conklin's theory ('12), that the yolk lobe is due to a weak spot in the protoplasmic pellicle, through which the lobe is forced out by "mitotic pressure," is inadequate. For this theory would not explain the non-appearance of the lobe in *Cirratus* at the third cleavage, though it appears in both earlier and later stages.

A Solution of the Problem of Yolk Manipulation by Ophiura: CASWELL GRAVE.

The egg of the brittle-star, *Ophiura brevispina*, contains a very large amount of yolk and in its cleavage and early development this yolk, in the form of minute spherules, is equally distributed to all of the cells.

In its yolk distribution it, therefore, does not differ from the eggs of other Echinoderms but does differ greatly from those eggs of Arthropods, Molluscs and Vertebrates which are rich in yolk. In the latter, the yolk is early segregated either into a few inert cells or into a portion of the egg from which the active cells withdraw during development.

In consequence of the large amount of yolk in the egg of *Ophiura* and of its equal distribution to every cell during segmentation and early development, a comparatively large amount of the energy of the egg is expended in the manipulation of its yolk content. For example: the resting cells of the blastula have the form of slender prisms, their length being to their breadth as nine is to one. During its mitosis, however, each cell becomes approximately spherical in shape. Connected with this enormous change in shape and position of a dividing cell, there takes place a very considerable readjustment of adjacent cells and their contents and especially an entirely new arrangement of the yolk spherules of the dividing cell.

The interesting observation herein reported is that this expenditure of energy in juggling with yolk spherules ceases when a stage in larval development is reached in which the gut and coelom are differentiated. At this stage the cells extrude practically all of their supply of yolk into

the blastocoel cavity. The redistribution of this mass of yolk to the tissues of the organism is a function of amœboid mesenchyme cells.

CYTOLOGY

The Nerve Centers of the Electric Organ in Raja Punctata: ULRICH DAHLGREN. (Illustrated with lantern slides.)

The X-element of Plymouth Rock Fowls: M. F. GUYER. (With demonstrations.)

Chromosomal Variations in the European Earwig, Forficula Auricularia: F. PAYNE.

Spermatogenesis in Chrysemys marginata and Cistudo carolina: H. E. JORDAN.

Chromidia appear to originate in the spermatogonia by a process of extrusion of chromatic particles from the nuclear recticulum. In *Chrysemys* the chromosomes during early growth stages are aggregated in or upon the nucleus; from here they disperse as small paired granules or rods; subsequently the chromosomes enlarge; the typical synapsis figure is absent. The nucleolar residue persists in part as a compact oval or paired-rod element, suggesting an accessory chromosome. The haploid number of chromosomes is 17, including one larger U-shaped element which passes apparently undivided (frequently as a pair of rods) and in advance of the other chromosomes to one pole of the first maturation spindle. In *Cistudo* a typical synapsis figure appears; the haploid number of chromosomes is 16; and there is no evidence similar to that in *Chrysemys* suggesting an X-element. Numbers of the secondary spermatocytes apparently divide amitotically, perhaps an abnormal condition.

A Microscopical Investigation of Tissues From Dogs Which Fasted Extremely Long Periods of Time: S. MORGULIS, P. E. HOWE AND P. B. HAWK.

The Germ-cell Cycle in Animals: R. W. HEGNER.

Of the nine periods into which the germ cell cycle in animals may be divided, two were discussed: (1) Cyst-formation in the testis of the potato beetle, *Leptinotarsa decemlineata*, and (2) the localization of the germ-cell substance in the unsegmented egg. At a certain stage in the multiplication period the spermatogonia of the potato beetle become each surrounded by epithelial cells. Each spermatogonium divides by mitosis and the daughter cells can be identified because of connecting strands—the remains of the spindle. These spindle-remains enable one to prove conclusively

that all of the spermatozoa in a single cyst arise from a single spermatogonium. These divisions constitute a period which parallels that in *Dytiscus* during which one oogonium produces fifteen nurse cells and one oocyte. The germ cell substance in many animals is localized in the unsegmented egg and can be distinguished by the presence of stainable inclusions which may be named keimbahn-determinants.

The Orientation of the Nuclear Organs in the Electric Motor Cells of Tetronaree and Other Torpedoes: ULRICH DAHLGREN. (Illustrated with lantern slides.)

Chromosomes in Opalina: M. M. METCALF.

The Physical Changes in Marine Eggs in Fertilization: G. L. KITE. (Illustrated with lantern slides.) (Introduced by C. E. McClung.)

The Molar Structure of Protoplasm: G. L. KITE. (Introduced by C. E. McClung.)

The conclusions presented in this paper are founded on the dissection of representative cells of widely different types of animals and plants. A detailed investigation of the principal kinds of cells of the frog and rabbit has been made.

Protoplasm has been found to be composed of gels and sols. With few exceptions resting nuclei are rather rigid gels which contain denser areas. Such areas are frequently arranged in the form of imperfect networks. The cytoplasm is usually in the gel state and may contain globules, granules and fibrils. The globules are completely separated from the imbedding gel, while granules and fibrils grade into the contiguous substance.

Dividing cells have proved to be of special interest. Chromosomes and spindle fibers seem to be incomplete separation products. The changes which result in the separations are at least partially reversible. Experiments on different kinds of dividing cells point unmistakably to the fact that the chromosomes and spindle fibers play a secondary rôle in indirect cell-division. The optically undifferentiated protoplasm, lying around and between the chromosomes and spindle fibers and in the plane of cleavage, is the portion that is the seat of the active changes that result in cell-division.

The chief general conclusion from this study is that protoplasm is a one-phased system in molar structure. Dissections of cells under quite satisfactory optical conditions have failed to reveal the contiguous solid and liquid phases that are generally held to be the essential elements of protoplasm.

GENETICS

A Male Gynandromorph of Colias (Eurytus) Eurytheme Showing Dimorphism in the Female Color Pattern: JOHN H. GEROULD. (Illustrated with lantern slides.)

Inheritance in Orthoptera: ROBERT K. NABOURS.

During five years many types with complex color patterns of *Parateletia* Bolivar, of the Orthopteran subfamily Tetriginæ, have been captured and bred in the greenhouse, for two years at the University of Chicago and three years at the Kansas Agricultural College, Manhattan. From these have been segregated through Mendelian analyses about fifteen true breeding types. These true breeding forms have been recombined to make all the original hybrid types and many others which have not as yet been found in nature. Ten true breeding types have been tried, and, with one exception, each has been found to pair with each of the others, making as many allelomorphic pairs as there are possible combinations. Some of the cultures have been carried to the F₂ generation, and some of the forms have been bred, in one combination or another, for sixteen generations. The results throughout have been typically Mendelian, except that one form, *P. melanothorax* (G), when crossed with any other form, produces F₁ progeny that do not always give gametes alternatively, but seem to give some gametes that represent both parents. For instance a *melanothorax* (G)—*leucocnotus* (B) hybrid mated with a *leucothorax* (C) homozygous form gives CG, BC and BCG progeny. Reciprocal crosses have invariably given identical results.

The Effect of Selection Upon Egg Characters in Parthenogenetic Lines of Hydatina: A. FRANKLIN SHULL.

Fifty Generations of Selection in Parthenogenetic Pure Lines of Daphniids: A. M. BANTA.

Selection experiments in pure parthenogenetic lines of daphniids were reported on. In all eighteen lines were continued under selection for eight generations or longer and eleven for from thirty to fifty generations. The daphniids belong to three species and were originally taken from several different ponds near Cold Spring Harbor. Fourteen of these lines are *Daphnia pulex*, two belong to another species of *Daphnia* and two are *Simoccephalus*.

The character used as the basis for selection was purely a physiological one, the daphniids' reaction to light. In the beginning of the experiment the

first brood from a young mother was placed in the experimental tank under carefully controlled conditions and while still only a few hours old. The first one of these young to reach the positive end of the tank was selected for the beginning of the + strain and the one last reaching the positive end, or failing to reach it within a given time, for the beginning of the — strain. In a similar manner the selections were made in later generations. To August first for the whole period during which selection had been continued the mean reaction time of the + strains of four of the lines was greater than the mean reaction time of the corresponding — strains, this indicating presumably a greater responsiveness to light on the part of the + strains in spite of the selection for the reverse effect. Two of these differences are statistically significant, as they are more than two and one half times the probable error. In fourteen of the eighteen lines the — strains have a higher reaction time than the corresponding + strains and in eight of these the differences are statistically significant. Of the lines selected for from thirty to fifty generations two have a higher mean reaction time in the + strain and nine in the — strain. The two former and six of the latter differences are statistically significant.

Size Differences in the Spermatozoa from Single Testes: CHARLES ZELENYA AND E. C. FAUST.

Measurements were made of the length of the head in five hundred or more spermatozoa of each of twelve species of animals. The variation curves plotted from these measurements were used in determining the probable presence or absence of size dimorphism.

In *Anasa*, *Lygæus*, *Alydus*, *Musca*, *Melanoplus femur-rubrum*, *Melanoplus differentialis* and *Phytanomonus* among insects and *Pseudomys* and *Bos* among vertebrates the curves are distinctly bimodal and indicate the presence of two size groups. The inference is made that the group of larger spermatozoa is the one with an X chromosome and the group of smaller spermatozoa the one without an X chromosome.

Segregation of Traits in a Pennsylvania Family: WILHEMINE E. KRY.

Some Reactions of the Shell of the Pond Snail, Lymnaea, to External Conditions: HAROLD S. COLTON.

A Quantitative Basis of Sex as Indicated by the Sex Behavior of Doves From a Sex Controlled Series: OSCAR RIDDLE.

By his method of controlling sex in pigeons Whitman showed (1) that the first young of the season (spring and early summer) were nearly all males, and young hatched from the later eggs of the season were nearly all females; (2) that if the two sexes arise from the two eggs of any one clutch, that it is in nearly all cases the first egg which produces the male, and the second egg of the clutch that produces a female; (3) that birds kept thus mated and overworked at egg-production tend to produce in succeeding years fewer and fewer males before the appearance of females.

A study of the sex behavior of the females of one such series (reciprocal cross of *T. orientalis* × *S. Alba*) has shown (1) that the females (dark in color) of the *alba* × *orientalis* cross are more masculine in their sex behavior (i. e., function more times as males in copulation) than the females (white in color) of the reciprocal cross; (2) that females of either cross hatched early in the season, i. e., closest to male-producing conditions, are more masculine in their sex behavior than their own sisters hatched late in the season from eggs produced under strongest female-producing conditions; (3) that two full sisters hatched from the two eggs of a single clutch most strongly contrast with each other. The bird from the first or male-producing egg of the clutch usually taking the part of the male to a full 100 per cent.

The injection (over a period of one month) of extracts and suspensions of ovarian tissue into the more masculine of these females, with simultaneous injections of testicular extract and suspension into the more feminine of the pair, has succeeded in some cases in very strongly reversing the sex behavior of the pair. The effect persists more than 25 days after the last injection.

The behavior itself, and the effects of the extracts, have been recorded on moving picture films.

These two results together with our very abundant data on the storage metabolism of the ova of these forms, and the initial fact of sex control itself, strongly indicate that the basis of sex is a fluid, reversible process; that the basis of adult sexual difference is a quantitative rather than a qualitative thing.

Size Inheritance in Rabbits: E. C. MACDOWELL. (Introduced by W. E. Castle.)

To test the hypothesis that the apparent blending inheritance shown by Castle's work on the ear length of rabbits may be interpreted by the multiple factor hypothesis established by Nilsson-Ehle,

these experiments were planned and started by Professor Castle. They were handed over to the writer in the fall of 1909. Crosses were made between rabbits of large and small body size; the offspring were crossed back to the parents to produce a back-cross generation. Based upon the statistical study of bone measurements and body weight as estimated from growth curves, it was found that the back-cross was more variable in size than the first generation. This was shown by standard deviations as well as by classifications of the actual measurements in relation to the parents. Certain measurements from the back-cross rabbits reached and exceeded the parental extremes. The means of both generations were very close to the mid-parentals in both generations. All these facts would be expected if the multiple-factor hypothesis be used to construct a mechanism to account for size inheritance. The increased variability would be due to a segregation of size factors.

CASWELL GRAVE,
Secretary

(To be continued)

THE ENTOMOLOGICAL SOCIETY OF AMERICA

THE eighth annual meeting of the Entomological Society of America was held at the Atlanta Medical College, Atlanta, Ga., December 30 and 31, in affiliation with the American Association for the Advancement of Science. In the absence of President Bethune, the meetings were presided over by Dr. Philip P. Calvert. The meetings were all well attended, there were about fifty members and fellows in attendance.

The following papers were presented:

"The Structure of the Hind Intestine of *Corydalis*," by J. T. Lloyd.

"Observations on the Habits and Life-history of *Hydromyza confluenta* Loew," by Paul S. Welch. (Read by title.)

"New Characters in the Classification of Microlepidopterous Larvæ," by Stanley B. Fracker.

"The Poison Glands of *Euproctis chrysorrhæa* Linn.," by Cornelia F. Kephart. (Presented by W. A. Riley.)

"The Tracheation of the Anal Area of the Wings of the Lepidoptera and the Homology of the Veins," by N. L. Partridge. (Read by title.)

"The Box-elder Bug in Ohio," by Herbert Osborn.

"The Elytral Tracheation of the Subfamilies and Genera of Cicindelidæ," by V. E. Shelford.

"Some Interesting Structures in the Pupæ of Lepidoptera," by Edna Mosher.

"Some Sources of Error in the Interpretation of Insect Tissue," by W. A. Riley.

"*Conventia hageni* Banks, Life-history Notes and Variations in Wing Venation," by J. S. Houser.

"Notes on the Head Structures of Thysanoptera," by Alvah Peterson. (Read by title.)

"The Desirability of a Biographical Dictionary of Entomologists," by Philip P. Calvert.

The afternoon of the thirtieth was devoted to a joint session of Section F of the American Association for the Advancement of Science and the Entomological Society of America, at which the following papers were presented:

"Note on the Present Status of the Gipsy Moth Parasites in New England," by L. O. Howard.

"Some Notes Regarding the Natural History of the Mole Cricket," by E. L. Worsham.

"Notes on Some Old European Collections," by H. T. Fernald.

"Studies on the Snowy Tree-cricket, *Eucanthus niveus*, with References to Apple Bark Diseases," by P. J. Parrott, W. O. Gloyer and B. B. Fulton. (Presented by P. J. Parrott.)

"Collecting Insects in the Okefenoke Swamp," by J. Chester Bradley. (Presented by J. G. Needham.)

"Studies on the Geographical Distribution of Leaf-hoppers, Especially of Maine," by Herbert Osborn.

"The Fauna of Epiphytic Bromeliads in Costa Rica," by Philip P. Calvert.

The morning of the thirty-first was devoted to the presentation of the report of the executive committee, at which was reported the election of fifty-four new members and the election of Dr. C. Gordon Hewitt and Dr. William Barnes as fellows; the presentation of the reports of standing committees; the election of officers; the adoption of the report of the committee to hold a summer meeting in 1915 on the Pacific coast; the appointment of a committee to consider the desirability of starting the publication of a series of special works on entomology like that of the Ray Society, and the reading of the following papers:

"The Dispersal of *Musca domestica*," by James Zetek. (Presented by S. B. Fracker.)

"A Comparison of the Enemies of *Toxoptera graminum* in South Africa and the United States," by William Moore. (Presented by F. L. Washburn.)

"Life-history Notes on *Psephenus lecontei* and *Hydroporus septentrionalis*," by Robert Matheson. (Read by title.)

"The Sequence of Color Changes During Ontogeny in *Cicindela*," by V. E. Shelford.

"Notes on the External Anatomy of Some Pentatomidae," by R. W. Leiby.

"The Biology of *Gelechia gallatolidaginis* with Some Reference to Some of Its Parasites," by L. S. Barber.

"A Little Known Wire-worm, *Horistonotus uhleri*," by A. F. Conradi.

"The Life-history of a Species of Psychodidae," by Leonard Hazeman. (Read by title.)

"The Structure of the Thorax in Generalized Insects," by A. D. MacGillivray.

"Behavior of *Anopheles tarsimaculata* Goldi," by James Zetek. (Read by title.)

"Life-history of *Elophila magnificalis*, an Aquatic Lepidopteron," by J. T. Lloyd. (Read by title.)

The following officers were elected for 1914:

President—Dr. Philip P. Calvert, University of Pennsylvania.

First Vice-president—Dr. James G. Needham, Cornell University.

Second Vice-president—Dr. C. Gordon Hewitt, Dominion Entomologist.

Secretary-treasurer—Dr. Alex. D. MacGillivray, University of Illinois.

Additional Members of the Executive Committee—Professor Herbert Osborn, Ohio State University; Dr. W. M. Wheeler, Harvard University; Professor Vernon L. Kellogg, Leland Stanford Junior University; Mr. Nathan Banks, United States National Museum; Dr. E. P. Felt, State Entomologist of New York, and Professor J. M. Aldrich, United States Bureau of Entomology.

Member of Committee on Nomenclature—Professor T. D. A. Cockerell, University of Colorado.

The next meeting will be held in Philadelphia, Pa., in affiliation with the American Association for the Advancement of Science.

ALEX. D. MACGILLIVRAY,
Secretary

SOCIETIES AND ACADEMIES

THE AMERICAN MATHEMATICAL SOCIETY

THE one hundred and sixty-eighth regular meeting of the society was held at Columbia University on Saturday, February 28. The attendance at the two sessions included forty-two members. Vice-president L. P. Eisenhart occupied the chair.

The following new members were elected: Mr. E. W. Castle, Princeton University; Professor P. J. Daniell, Rice Institute; Mr. L. R. Ford, Harvard University; Mr. C. M. Hill, State Normal School, Springfield, Mo.; Dr. R. A. Johnson, Adelbert College; Dr. L. M. Kells, Columbia University; Dr. W. W. Küstermann, Pennsylvania State College; Professor J. F. Reilly, State University of Iowa; Professor F. B. Williams, Clark University. Nine applications for membership were received.

An amendment of the constitution was adopted by which the secretary of the Chicago Section becomes *ex officio* a member of the council.

The following papers were read at this meeting:

H. S. Vandiver: "Note on Fermat's last theorem."

G. M. Green: "One-parameter families of space curves, and conjugate nets on a curved surface."

G. M. Conwell: "Brachistochrones under the action of gravity and friction."

R. D. Beetle: "A formula in the theory of surfaces."

C. A. Fischer: "The Legendre condition for a minimum of a double integral, with an isoperimetric condition."

A. R. Schweitzer: "A generalization of functional equations."

A. R. Schweitzer: "Some critical remarks on analytic realism."

E. V. Huntington: "A graphical solution of a problem in geology."

H. Galajikian: "A relation between a certain non-linear Fredholm equation and a linear equation of the first kind."

Dunham Jackson: "Note on rational functions of several complex variables."

E. B. Wilson: "Infinite regions in geometry."

H. Bateman: "The structure of the aether."

F. R. Sharpe and Virgil Snyder: "Birational transformations of certain quartic surfaces."

F. R. Sharpe and C. F. Craig: "An application of Severi's theory of a basis to the Kummer and Weddle surfaces."

B. E. Mitchell: "Complex conics and their real representation."

W. H. Roever: "Analytic derivation of formulas for the deviation of falling bodies."

The next meetings of the society will be held at Chicago, April 10-11, and at New York, April 25.

THE ACTION OF VITAL STAINS BELONGING TO THE BENZIDINE GROUP¹

THE brilliant advances in our knowledge of the chemistry of aniline dyes, brought about naturally by the enormous commercial importance which the dyes possess, has been brought to bear, and will in the future be brought to bear, we believe, in the solution of some important problems in biology. The dyes possess peculiar advantages; especially is this true in the case of those of them which undergo little or no chemical transformation when injected into the living body. To this class of dyes, as we hope to show later, belong the benzidine or substantivative dyes. It might be inquired immediately whether vastly more important results could not be secured from the study of dyes which, on the contrary, are known to suffer definite chemical changes within the body, for it might be supposed, for instance, that valuable light could be thrown on oxidative or reductive processes peculiar to certain cells or tissues. It was, of course, with motives not far removed from these, that Ehrlich first seriously attempted the use of dyes to solve the problem of the relation between pharmacological action and chemical constitution in his classical essay on this thesis in 1902. When we insist, however,

¹ Read at the session of the National Academy of Sciences, Baltimore, November 18, 1913. From the Anatomical Laboratory, Johns Hopkins University and the Kgl. chirurgisches Institut, Breslau. The study is a preliminary report of observations which will be presented in full in the Memoirs of the Rockefeller Institute for Medical Research and which were rendered possible by grants from the Rockefeller Institute and the Robert Koch Stiftung, Berlin.

that the study of dyes which suffer no chemical change within the body is of the highest value and indeed calculated to lead us to results which can be secured in no other way, we do so mainly because the class of dyes to which we refer can be injected in relatively large quantities into the blood stream of living animals without perceptible toxic effect; and the dye, taken care of as it were by definite cells which store it unchanged within their cytoplasm, can be detected without difficulty, wherever it may be, on account of its color.

In 1905, Ehrlich and Shiga, then attempting the cure of trypanosome infections in laboratory animals, happened to find that the azo dye, which they named trypan red and which possesses the following formula:

could be injected in sufficient quantity into the living animal to kill the organisms of the disease without perceptible toxic effect to the cells or tissues of the host, themselves deeply stained. A year later, driven thither in the same quest, Nicolle and Mesnil, of Paris, discovered a similar effective compound or "good color" as they called it in trypan blue, a dye formed by the combination of two molecules of 1.8 amido-naphthol 3.6 disulphonic acid with one molecule of diazotized ortho-tolidine in alkaline solution.

The profound color of the healthy animals which received this dye could not fail to attract the attention of Nicolle and Mesnil, who set Boufard the fascinating problem

of determining in what form the dye persisted in the body. His report, which was all too short, nevertheless acquainted us with the main fact that the dye had not merely remained in the fluids of the body or had pervaded the organs and tissues in a profuse way, but was engulfed in the bodies of certain definite cells primarily of one type which we shall have occasion to describe carefully shortly. Coincidentally Goldman at Ehrlich's suggestion took up the same theme, and his enthusiastic studies have in spite of occasional inaccuracy attracted general interest to the subject.

Nowhere however in the rapid literature which has begun to accumulate on this subject can one find an attempted answer to the fundamental question of how the dye really acts on the cells of the body, *i. e.*, what property it is by virtue of which one of the members of this class of dyes is enabled to be a brilliant vital stain; whereas a closely related dye is a complete failure. Nor, secondly, does it seem to me that full advantage has been taken of the great opportunity bestowed by these dyes in enabling us to detect a hitherto unknown or unrecognized function of a great mass of cells all over the body which can now be grouped together under a common designation as a great system or tissue.

If we inject into the peritoneal cavity of a mouse 1 c.c. of a one half per cent. solution of trypan blue, we can observe within a few minutes that the ears, the tip of the nose, the tail, the mucous membranes and soon the skin of the entire body have begun to blue, and that this deepens rapidly in intensity, so that within a few hours a maximal deep blue color is possessed by the animal, a color which, in spite of this single dose, is not lost for many weeks. The animal thus stained plays, eats, breeds, and in all ways manifests its normal activity, and

there is no evidence of the ill effect of the dye.

If now instead of trypan blue we employ the brilliant blue dye azo-blue whose constitution is

we are met by a striking difference. Neither within minutes or hours after the intraperitoneal injection of such a dye is any trace of color to be seen from the dye, and the repeated injection of the dye over a long period of time does not in any way change this negative result. The autopsy of such an animal shows indeed that we have heaped upon it a large quantity of a colored foreign body, for the dye has remained on the whole where it was injected, that is, in the peritoneum and the structures connected with it. Why this difference?

Several notions have been advanced in explanation of the action of vital stains. Primarily we have to do with the ideas, first, that a chemical union exists between the dye molecules and some portion of the cell protoplasm, and, second, the theory that dyes owe their ability to stain vitally to some physical property by virtue of which they can penetrate the cell. The name of Ehrlich is connected with the first of these two views, while that of Overton is identified with the second, and we may mention here that the commonest physical rather than chemical explanation of vital staining has been that the dyes in question are soluble in fat or fat-like bodies, a layer of which was assumed to envelop the cell. While this explanation may have been convincing in the explanation of vital staining obtained by the earliest known vital stains (methylene blue and neutral red) we are

aware now that both of the assumptions involved in it were gratuitous, for neither are the benzidine dyes soluble in fats or lipoids nor are the majority of the cells of the body surrounded by a layer of these substances. If, then, in spite of the above, we must maintain that after all physical factors play a predominant rôle in the vital staining produced by the azo or benzidine dyes, it is for reasons quite apart from those involved in Overton's lipid theory.

The chemical explanation of a vital stain presupposes that there exists between some element of the protoplasm of the cell, the chemo-receptor in the sense of Ehrlich, and some part of the dye molecule a combination, such as we are accustomed to see take place between two bodies in accordance with the laws of formal valence. It is only necessary to show how important such an explanation is in the mind of Ehrlich by mentioning the fact that he assigns the therapeutic effects of the drug salvarsan primarily to an affinity which he assumes to exist between the parasites of syphilis and a precise part of the salvarsan molecule; namely, the ortho-amido-phenol configuration. The application of this principle in an explanation of the vital stain produced by trypan blue must lead us to maintain that a similar configuration, *i. e.*, the peri-amido-naphthol configuration, is really responsible for the union between dye and cell which gives us the vital stain here. We can dispense with such reasoning shortly.

Evidence which would appear to concern the efficacy of a peri-amido-naphthol ceptor is furnished by the brilliant vital staining produced by the dyes Nos. 1824, 1835 and 1846, in all of which the hydroxyl and amido groups are in a peri position to one another, and the azo bond at position II.

No. 1824

No. 1835

No. 1846

Furthermore, the production of exactly as brilliant a result by dyes in which merely the position of the OH group has remained constant, the NH₂ group either being absent or shifted in its position, might lead us to suppose that it is the alpha position of the hydroxyl radicle rather than the entire peri-amido complex which in all these cases has determined the vital stain. We mention of such dyes the vital stains 2836, 1836 dioxo, 1527, 136, 1368.

No. 2836

No. 1836

No. 136

No. 1527

No. 1368

This conclusion, however, (*i. e.*, that an alpha-naphthol receptor has been responsible for the staining) must be rejected at once as soon as we examine the dyes 184, 185, 257, 258, 286, 184 dioxo 14 and 15 all of which can be injected into animals without producing a vital stain.

It is apparent then from the foregoing that if the alpha-naphthol receptor is to work, it can only do so in the presence of two sulfonic acid groups.

When, now, we examine the behavior of the beta-naphthol sulfonic acids in this respect, we find that, strangely enough, one of the monosulfonic acids (namely the 2.8 acid) produces a dye which acts as a vital stain.²

The other mono acids which we have examined (the 2.6 and 2.7 acids) produce entirely negative dyes.

No. 26

No. 27

Whereas of the disulfonic acids, the 2.3.7 and 2.6.8 acids produce dyes which are non-stainers, the 2.3.6 acid combined with toluidine furnishes a dye which approaches a true vital stain.

No. 237

No. 268

A comparison of the different effects secured by the two dyes 236 and 237 is interesting, for it is difficult to believe that the exact position which the sulfonic acid radicle assumes in the naphthalene ring is an adequate explanation of this. In all the dyes which we have examined, the number of sulfonic groups has been important, but not the position which they occupy. The precise point of insertion in the naphthalene ring was of little moment and we have to inquire in dyes 236 and 237 why the shifting of one SO_3Na group from 6 to 7 changes a positive into a negative dye. Now these two isomeric acids, apart from their close chemical relationship, have long been known to produce dyes which differ greatly in some of their non-chemical characteristics—characteristics which we believe determine whether a dye of the benzidine class shall be a vital stain or not.

For the present, however, let us believe that there is a general alpha-naphthol-disulfonic ceptor, a particular beta-naphthol-disulfonic ceptor (viz., the 236 one) and a particular beta-naphthol-monosulfonic ceptor (the 28 one) whereas none of the other monosulfonic and none of the other beta disulfonic acids have chemoceptors corresponding to them in the cell.

When we consider the dyes made from the naphtylamines we must still further extend our list of hypothetical chemoceptors, for many of these dyes are brilliant vital stains, among them 13, 15, 16, 26, 27 and 28.

Both of the naphthylamine disulfonic acids with which we have worked have yielded equally brilliant results (the 2.3.6 and 1.4.8 ones).

No. 236

No. 148

We meet, however, among the naphthylamines surprises which are just as remarkable as those which greeted us in the naph-

tol group, for the isomeric dyes which are listed below (12, 14, 17, 18 and 25) are all negative.

We shall not have to insist that it is hardly likely that chemical reaction between these dyes and substances with which they could truly combine would hardly occur or fail to occur in this capricious way. Our results then are hardly capable of being formulated in terms of the chemoceptor theory, for there is no one chemical configuration which we are able to pick as a chemoceptor. Our search at this juncture for some common characteristic possessed by a positive in contrast to negative dye, a characteristic which when possessed always permitted the dye to be a vital stain and when absent led us to predict its failure, was rewarded with success. We were in short induced to look into the phys-

ical state of the dye solutions. Our attention was rather dramatically called to this phase by experiments with benzo-purpurine B:

A fresh, cold one-per-cent. solution of this dye can be injected rapidly into the ear vein of the living rabbit and will produce within a few minutes a beautiful diffuse coloring of the whole animal, a coloring which though at first affecting merely the body fluid, can in a few hours be seen to have established itself in the form of granules in that distinct class of cells which are affected by dyes of this group. If, on the other hand, we inject a similar cold solution of this dye, but one which has been allowed to stand a few days before using, the animal invariably dies before our eyes with typical symptoms of cerebral embolism. If we boil the dye for a little while with Ringer's solution instead of with water, the effect is even more marked, for a single cubic centimeter of such a solution after it has been allowed to cool, kills the animal instantly on injection. Why are the dye solutions so different in their behavior? A few test-tube experiments sufficiently answered our question, for we were dealing with an electrolytic precipitation of a colloid, whose coagula were sufficient to plug the cerebral vessels. By testing in this way all of the dyes which we have reported as negative, we were able to show that no one of them failed to produce embolism on injection.

But while thus dangerous in the living blood stream there might still be thought to be no reason why these dyes should fail to act when placed under the skin or in the body cavity. In these situations, however,

the dyes remain without invading much of the remainder of the body, and we were led to test the diffusion power of positive and negative dyes in a medium where it was slow enough to be measured, *i. e.*, in 2 per cent. gelatin, and without presenting here our tabular results we found no exception to the rule that positive dyes possessed a rapid diffusion rate, while negative dyes little if any diffusion at all.

These facts harmonize, of course, perfectly with our knowledge of the behavior of colloids, and make it certain that we are dealing with phenomena which depend on the size of the particles or aggregates in our solution. A negative dye could not reach many cells in the body, for its particles are all large and rapidly agglutinated in the body fluids, and such large particles have slight, if any, power of diffusion. Did, however, the cells in their neighborhood accept these negative dyes?

The investigation of the cells of the subcutaneous tissues at the injection site showed that even with the most negative dyes a vital staining in this limited zone had always taken place. Our failure to stain more cells than was due solely to our inability to reach them. We proved this contention, we believe, conclusively by selecting a dye D-14.

which when placed under the skin has practically no powers of diffusion and which when injected at a normal rate into the blood stream always kills with the typical picture of embolism. We found that the very slow injection of a perfectly fresh, cold one half per cent. solution in distilled water obviated this accident; and although for a few days the continual injection of

the dye did not color the skin or mucous membranes of the animal, this was eventually obtained. The study of an animal in the early stage of such a series of injections is most interesting. We have indicated that such a negative dye must consist chiefly of large particles, and since little color appears in the urine of these animals, and the animal is externally unstained, it is evident that the dye particles are engulfed by cells internally located. The autopsy of such an animal shows that not only the skin but most of its tissues are free from dye with four notable exceptions; namely the liver, the spleen, the lymph-glands, and the bone marrow, all of which are blue-black.

We do not believe that a heightened power to attract the dye is possessed by the cells in these localities. The skin cells in the neighborhood of a puncture take up the stain almost as rapidly, but they are unable to do it when the large dye particles are only circulating in the blood vessels, from which their lack of diffusion powers never take them, for they can not leak through the walls of the capillaries.

A glance at the list of positive and negative dyes which is just presented shows us that most positive dyes are disulfonic acids, a statement, in view of the ideas which we have just developed, which means that the sulfonic acid radicle exerts a favorable effect on the character of the dye solution, *i. e.*, makes it more soluble, more diffusible, and, so, quickly distributed, that is, a *true vital stain*. Evidence to this effect has already accumulated in a comparison with the positive and negative dyes 184, 185, 1846, 1824 and 1835, but this conclusion is, we think, substantiated in a more complete and overwhelming way by the sulfonation of a number of negative dyes by which means brilliant, positive stains were always secured. We cite as a good example of this

Identical results were secured with the 2.8 amido naphthol 6 sulfonic acid combined with benzidine, with benzidine monosulfonic acid and with benzidine disulfonic acid; and a similar effect of sulfonation is seen in the brilliant tetra-sulfonic congo red dye made from the 1 naphthylamine 4.8 disulfonic acid, whereas the congo red monosulfonic acid (the 1 naphthylamine 4 sulfonic acid) or naphthionic acid yields a dye which is not a vital stain.

In this connection the question of whether or not it was possible to over-sulphonate the dye was attempted with interesting results. The sulfonation of diamine blue 2B gives us a dye which while a vital stain nevertheless passes the kidney much more rapidly than the original body, so that after an intense stain the animal is decolorized again in a few days. We have secured identical results in experiments with a similar sulfonated trypan blue.

The staining with acid azo dyes then is a physical phenomenon, and when we turned our attention to the likelihood of other solutions or pseudo-solutions giving an identical picture we are able to say that such is indeed the case, for those excellent suspensions of fine particles of gold, silver, palladium and some other metals which are called colloidal solutions eventually stained an animal just as did our vital dye. This effect has in fact been known for a long time for the so-called argyria, a pigmentation of the mucous membranes of workers concerned with silver salts, is a similar storage of particles formed by the silver when it meets the fluids in the body.

It remains now to discuss briefly what cells or tissues in the body are selectively affected by these stains. We can do this best by describing the autopsy of an animal which has been injected, on two occasions three days apart, with trypan blue and killed the day following the last injection when the animal with every appearance of health is intense blue. The skin of the abdomen when stripped back is seen to be intensely stained, but freshly spread preparations from the subcutaneous tissue show that the color is only to a minor degree due to the coloration of the fluids, but mainly to great numbers of small though dense granular deposits in certain cells. The larger and more striking of the cells possess a large slightly irregular oval nucleus, and an elongated cell body with frequent though always sharply defined pseudopodia or larger cell processes. Irregularly scattered through the cytoplasm are the granular deposits of the dye, and the larger of these are always comprised in a vacuole inside of which both larger and tinier fragments are in liveliest Brownian movement. We have identified these large, brilliantly stained cells of the skin and connective tissue of the body as the cells which have

been designated variously by histologists as the resting wandering cells (Maximow); the clasmatoocytes (Ranvier), the adventitia cells (Marchand) and the rhagiocrine cells (Regaud). At the same time in smaller, although more abundant cells, cells with more regularly oval nuclei and with faintly defined nuclear membrane and cytoplasmic boundaries, in these cells are fine scattered granules of the stain. These are, we believe, the most abundant and typical cells of connective tissue and are probably those designated as fibroblasts by the majority of investigators. None of the blood cells nor the endothelial cells of the capillaries of the skin carry the minutest trace of the dye. The muscles of the body, instead of their customary pink hue, are greenish in color, due to the infiltration in the minute connective tissue septa of countless numbers of these vitally stained cells of both types. The peritoneal cavity contains a normal amount of fluid which is pale blue in color and in which are suspended many vitally stained cells. The most brilliant of these and the largest are those cells which have been designated by Mechnikoff, Schott and others as makrophages—cells which, spherical in shape, are covered with delicate pseudopodia, and the cytoplasm of which is often a frothy mass of vacuoles, in which are always particles of the dye. We can trace all transition stages from these cells to those but slightly larger than lymphocytes, all of them containing some inclusions of the vital stain.

The cells which line the peritoneum, the mesothelial cells of Minot, possess in a peripheral zone the fine granulations which are characteristic of the cells of type 2 in the skin.

Of the peritoneal organs the liver and kidney are undoubtedly the deepest stained, for they are almost a blue black, a color due in the liver almost exclusively to the inclu-

sions of the dye by the cells of Kupfer of the hepatic capillaries and in the kidney to a similar behavior shown by the epithelial cells of the proximal convoluted tubules. The spleen and lymph glands are stained a paler though still brilliant blue and the color is due in these organs to the granules carried by the so-called reticular and by the true lymphatic endothelial cells.

In the testis the interstitial cells of Leydig are stained brilliantly, although the granules here are singularly regular and intermediate in size between those possessed by cells of type one and two in the skin. In addition, true vitally stained connective tissue cells of type two are also present between the seminiferous ducts, but the epithelial cells of the seminiferous tubules never contain the slightest trace of the dye.

The pancreas possesses in the connective tissue septa of its acini brilliantly stained cells of type one, although no particle of the dye is found in the pancreatic parenchyma.

The thoracic cavity presents a remarkable picture, for its deep blue walls enclose the lungs which have preserved their normal pink color, and in which few vitally stained cells are found. The heart, however, contains many of these, for not only do the epicardial cells receive the dye like the mesothelial ones, but also many connective tissue cells of type one infiltrate its musculature at many points.

The thymus, thyroid and parathyroids owe their generally lighter stain to similar cells which follow the connective tissue in its structural relation to these organs.

Most remarkable is the behavior of the central nervous system, for with the exception of the hypophysis and choroid plexus the nervous system contains no trace whatever of the dye, and its whiteness in contrast to the stain of the other tissues is a strange sight, the more so because the dura is always densely stained.

With the exception of the kidney, the epithelium of whose convoluted tubules comes from the middle germ layer, the great mass of the epithelium of the body refuses to react to the stain. Most remarkable also is the rejection of the dye by the blood cells, whose polymorphonuclear elements have always been supposed to play so great a rôle in phagocytizing foreign particles.

It might possibly be supposed from the comparative physical measurements we have made on the dyes that the so-called vital stains or vital granules, which we have just described, are an expression merely of diffusion, especially inasmuch as the most diffusible dyes of this class are the most satisfactory vital stains; but we have explicitly pointed out that heightened diffusion powers effect the vital stain merely by enabling the dye molecules or dye-molecular-complexes to present themselves to the class of cells which will receive them in every corner of the body. Having arrived at the cell, the dye by no means diffuses into it, as we can see, for instance, various basic dyes (neutral red, methylene blue, janus green) diffuse into a cell, advancing from periphery to center, and lodging often with special avidity in some pre-formed granule or structural element of the cell (*e. g.*, mast cell granules with thionin or neutral red, Nissl bodies with methylene blue). The benzidine dyes, let in more slowly at the cell's periphery, never encounter physical conditions which favor their rapid spread and they are disposed of by the cell by being concentrated at various points where they are doubtless set apart from the cell's protoplasm. The vital granules then deserve their designation, for they are always the result of the behavior toward the dye on the part of a living cell. Dead cells behave quite differently, for into their protoplasm, including the nucleus, the benzidine dyes diffuse rapidly, produc-

ing a uniform stain. Nothing is more striking than the way in which dead cells are stained in this manner. Liver cells selectively poisoned by chloroform³ and renal cells killed by sublimate⁴ both permit an immediate diffusion of the dye into them and resultant stain; and even the nerve cells, normally hostile to the entry of a single trace of the dye, receive it similarly when killed, an elegant example of which is furnished by the anterior horn cells in experimental poliomyelitis.⁵ When we tap the cover slip over leucocytes swimming in trypan-blue, mechanical injury to the immediate subjacent cells invites instant entry of the dye.^{5a}

It is evident then that into the dead cell a true diffusion takes place, but if diffusion be acting at all in the case of those living cells which react to the vital stain it is at least seriously hampered. There is in fact no reason for the identification of the vital stain with a diffusion phenomenon. It is significant that the cells which take the benzidine dyes are predominantly those endowed with powers of phagocytosis, a process long known to be operating in the case of particles from approximately 10 to 1 micron in size but it is not improbable that the colloidal particles of the benzidine dyes, whose dimensions must lie below a hundredth of such size, are received into the cell in an essentially similar way. Owing to their comparative minuteness, however, these particles are enabled to gain entry into many cells quite incapable of receiving larger ones. The fibroblast and mesothelial stains are examples of this. Yet in none of these cases does the cell, as it were, drink

in the dye particles, as it does the freely diffusing ions of a salt solution. Nor indeed are the dye molecular-aggregates phagocytized in the usual acceptance of the term, for there is not merely a protoplasmic flow around a foreign body. Countless ultramicroscopic particles of the foreign body are let into the peripheral protoplasm and collected in the more central lying deposits which we can at last recognize under the microscope as the dye granules.

This moving together or centralization of the dye in granules is not a reaction peculiar to the dyes, for an identical phenomenon is seen when colloidal silver is used, in which the particles have dimensions also considerably below the limits of ordinary microscopic vision and far below the dimensions of the intra-cellular granules in which they are later agminated.⁶ Yet we have never hesitated to speak of the phagocytosis of silver aggregates in this later case.

We have to do then, in the case of cells which are stained vitally by these dyes, with a great host of elements scattered all over the body, serving in some special organs as the lining of blood and lymph vessels, but in the great interstitial tissue of the body without the vessels, equally abundant, cells whose primary function seems to be the engulfment of particles whose physical dimensions fall within certain limits. These scavenger cells, as it were, rid the blood and tissue juices of many kinds of useful and unuseful débris. How they do this may still be difficult to explain, but there seems no doubt but that their protoplasm in contrast to that of epithelial cells consists of a peculiar physical system.

⁶ Bechold (*Zeitschr. f. chemie und Industrie der Kolloide*, 2 Jhrg., heft 1, 2) has determined that the aggregates of collargol-Heyden have a diameter of 20 μ . They consist of aggregates of metallic particles and particles of the schutz-kolloid together.

That useful and unuseful *débris* occurs normally in the body needs not, we take it, be defended, for the continual breaking down of some cellular elements of short life, the red blood corpuscles, for example, set free substances whose physical dimensions enable them to be engulfed by many of the cells which we have described (occurrence of blood pigment in liver, spleen, lymph glands and bone marrow) but that this reaction needs by no means be considered as one adapted for the engulfment of bodies of this class is proven conclusively by a number of observations made very recently by Ciaccio and others which go to show that fatty acids and lipoid substances are stored by the same cells. We are concerned then with cells of great physiological importance to the organism, cells whose action in this capacity, we believe, seems proven to be conditioned by physical and not chemical forces of response.

HERBERT M. EVANS,
WERNER SCHULEMANN

COMPARATIVE REGISTRATION STATISTICS¹

ONE of the greatest difficulties encountered in the compilation of comparative university statistics is found in the apparent impossibility of securing uniformity. This difficulty is owing in large measure to two factors, one quantitative and the other qualitative. An illustration of the former is furnished by the fact that the student attending six weeks of summer session is recognized as a full unit, just as much as the student of an engineering school who annually puts in thirty-six hours a week for two half-years and several weeks in camp; and similarly a person engaged in secondary teaching who registers for a single late-afternoon or Saturday morning course counts as a full unit just as well as a candidate for the doctorate who spends his entire

time at the university. Again, there are the students in so-called short courses, in agriculture, for example, who receive as much recognition as those who spend the entire year at the university. As a matter of fact, the most satisfactory solution along this line would be found in adopting a student-hour unit, but this, from the very nature of the case, would be an extremely complicated procedure. A simpler solution is reached by separating the summer session and short course students from those attending the entire year, and similarly by separating the full time from the partial time students. A difficulty would arise in connection with the point at which the line between these two groups is to be drawn, but this could readily be adjusted by agreement between the institutions involved. In this connection it might also be pointed out that owing to the fact that many secondary schools graduate classes in January as well as in June, several colleges and universities are admitting new students in February; they spend only half a year at the institution, but are counted as full units. On the other hand, the number of regular students enrolling for work in the summer session in order to reduce their time of residence or to make up conditions is constantly on the increase.

So far as the qualitative distinction is concerned, it must be borne in mind that the size of a university gives no more indication of its efficiency than the population of a country does of its degree of civilization, or the size of a city does of the morals and social welfare of its inhabitants. Comparative registration statistics, as they have been published by the writer from time to time in *SCIENCE* and elsewhere, have therefore little qualitative significance, inasmuch as such items as standards of admission and advancement, efficiency of instruction, equipment, and the like, are necessarily ignored in the comparison. So far as we are concerned in the present instance, standards of admission constitute perhaps the most significant item. No student should, in my opinion, be counted in the enrollment of a university, who has not offered graduation from a secondary school for admission. For-

¹ Paper presented at the annual meeting of the American Association of Collegiate Registrars, Richmond, Va., 1914.

unately the admission requirements in this country, owing to the influence of the Carnegie Foundation, the Association of American Universities, the American Medical Association and similar organizations, are being rapidly increased all along the line, but courses are still offered at several universities in which high-school graduation is not demanded for admission. The students registered in such courses should be rigidly excluded in the university total, but it is not always an easy matter for the outsider to determine who these students are, and consequently our sole dependence lies in the cooperation of the reporting officers of the institution concerned. Of less importance, though not entirely without significance, is the difference that still exists in entrance requirements for the professional schools, several of which insist upon a bachelor's degree, while others are still satisfied with high school graduation. It would seem that a student in a medical school who holds a bachelor's degree would have greater qualitative value, other things being equal, than one who has entered the school directly from the high school. The adoption by so many institutions of the so-called Columbia or combined-course plan, in accordance with which six years are devoted to work for the bachelor's and the professional degrees, is bringing about a certain amount of uniformity in this direction. Yet even where college graduation is demanded for admission to the professional schools, and more particularly to the non-professional graduate schools (political science, philosophy, pure science), some difficulty is encountered, inasmuch as the bachelor's degrees of American colleges are unfortunately not of equal value, and for that reason a number of graduate schools do not accept graduation from certain specified colleges for admission. This is a matter which only time can remedy, and fortunately there are indications that the work of these inferior institutions is slowly but surely improving. Comparative statistics of the professional schools showing the percentage of college graduates enrolled in these schools are therefore of distinct value.

A word should be said concerning the inclusion of extension students in the grand total enrollment of a university. As a matter of fact, extension students are frequently, quantitatively as well as qualitatively, on a par with summer-session students. They are, in many instances, at several institutions in most instances, graduates of high schools following work of college or university grade given by regular officers of the institution concerned, and there seems to be no reason why an extension student registered for a graduate course in literature should not be counted in the university's total with as much justification as the high school teacher who is enrolled as a candidate for the master's degree but attending only a single Saturday morning course. On the other hand, extension students are from the very nature of the case practically all partial-time students, and for this and several other reasons it is safer perhaps to keep them in a category by themselves. Auditors in attendance on a six-hour lecture course should not be included at all, as they sometimes are.

Considerable difficulty is constantly experienced in prevailing upon reporting officers to eliminate the item of double registration. The ideal table of comparative registration statistics would simply ignore this item; where it is not ignored, an element of unfairness is at once introduced. The student should be considered primarily registered in one faculty only, and if he happens to be enrolled in a combined course, he should, for example, in his third and fourth years as a candidate for the bachelor's degree, which coincides with the first and second years of his candidacy for the medical or engineering degree, be counted either as a college student or as a medical or engineering school student, but not, as is frequently done, as both. The latter method unduly swells the size of the individual faculties of the institution. Similarly, the students at Columbia University enrolled as candidates for the master's or the doctor's degree and with the major subject in education should be included either in the faculty of philosophy or in Teachers College, but not in both. In

such cases a footnote can readily be added calling attention to the actual state of affairs. Where the enrollment at a summer session is included, the item of double registration giving the number of students in attendance on the summer session who returned for work in the fall is of course unavoidable.

So far as the individual tables of statistics prepared by the office of the registrar are concerned, I consider the geographical distribution figures as among the most valuable, especially in view of the fact that these are not prepared by the Commissioner of Education. In the preparation of these statistics it should be borne in mind that students are often inclined to enroll from the town or state in which the institution in question is located, instead of from their actual home. A distinction should be drawn, for example, between the Chinese student who spends four years in this country and returns to his native land, and the student from Germany who enters one of our professional schools and contemplates remaining in this country. Statistics of birth are also valuable, although rarely compiled. This applies also to statistics indicating the vocations of the students' fathers.

In connection with tables illustrating changes in enrollment covering a period of years, attention should also be called to the *percentage* of increase (or decrease), which is usually more valuable in connection with comparative statistics than a mere statement of growth in student units.

So far as tables illustrating specific items of registration are concerned, I would respectfully recommend the suggestive tables and diagrams included in the recently published annual report of the registrar of the University of Illinois, which possess the merit of simplicity and clearness.

In my opinion the wide distribution of university statistics is just as valuable as the dissemination of statistical material compiled by the census office, only it must always be borne in mind that in connection with an educational institution size is by no means a primary consideration. Entirely as much fault may be found with an overgrown de-

partment, school or university, as with an overgrown boy, city or potato. It is always necessary, in the case of comparative figures, to read between the lines, although there is no doubt of the fact that not infrequently the large enrollment in a particular school is due to the well-deserved reputation which this school enjoys, as witness the Harvard Law School, the Johns Hopkins Medical School and the Columbia Graduate School. Any attempt, however, especially on the part of overzealous alumni, to overemphasize size at the expense of efficiency, should be deplored. In this connection the following paragraph in the last annual report of President Butler will be of interest:

The popular mind is easily impressed with size, and particularly with large numbers. The fact that Columbia University has under its influence and instruction many thousands of students is annually heralded in the public press as entitling it to claim precedence over other institutions at home or abroad. Within the university itself no such feeling prevails. The growth in numbers so marked in recent years, is, of course, gratifying in so far as it indicates that the curriculum, the equipment, and particularly the teachers and investigators of Columbia are sought on their own account. But we deplore growth in numbers unless it were accompanied by a steady increase in the quality of the students. . . . What should concern us is the quality, the character and the homogeneity of the several units of which the total is composed.

RUDOLF TOMBO, JR.

COLUMBIA UNIVERSITY

ARTHUR HENRY PIERCE

ARTHUR HENRY PIERCE, for fourteen years professor of psychology at Smith College, died of pneumonia, after a brief illness, on February 20, at Northampton, Mass. He was born in Westboro, Mass., July 30, 1867. He graduated at Amherst in 1888 and for two years thereafter taught mathematics in the college. His post-graduate studies in psychology were pursued at Harvard, where he received the master's degree in 1892 and the doctor's degree in 1899, and at the universities of Berlin, Strassburg and Paris, which he frequented in the years 1894-1897. He was the first holder

of the Kellogg University Fellowship, his tenure of which lasted from 1894 to 1900. In 1900 he was appointed professor of psychology in Smith College. He was an active member of the American Psychological Association, being for three years its secretary (1908-1910) and for another three years a valued member of the council (1911-1913). For the past four years he was editor-in-chief of the *Psychological Bulletin*. His first contribution to psychological science was an investigation on phenomena of attention conducted in collaboration with J. R. Angell in the Harvard laboratory and published in 1892. Two years later he published a paper on the localization of sound. For several years he made a careful study of geometrical-optical illusions. The results of these researches were collected into a volume, the "Studies in Auditory and Visual Space-Perception," published in 1901. Since then his attention as a psychologist was largely given to phenomena of dreams, hypnosis, subconscientness and synesthesia, in which field the most important of his publications was the noteworthy paper entitled, "An Appeal from the Prevailing Doctrine of a Detached Subconscientness," published in the Garman memorial volume in 1906.

Arthur Pierce was a man of singular breadth, balance and clarity of mind, of equable temper and of rare personal charm. All his work as teacher, investigator and administrator was marked by thorough conscientiousness and careful attention to details. His cheerful disposition, his unvarying courtesy, his quick, yet unobtrusive, sympathy, his resourcefulness and his practical good sense made him universally admired and beloved and his loss will be deeply and widely felt not only by his psychological colleagues, but by many in diverse walks of life who counted him as a loyal friend.

H. N. G.

THE FAIRPORT BIOLOGICAL STATION

THE biological laboratory of the United States Bureau of Fisheries, Fairport Station, will be opened for general biological investigations in the early part of the coming sum-

mer. This is the first permanent laboratory established by the government for the special study of freshwater biology and problems relating to freshwater fishery resources. The station is located on the Mississippi River twenty miles west of Davenport and eight miles east of Muscatine, Iowa, on the main line of the Rock Island railway between Chicago and Kansas City. Chicago, Milwaukee and St. Paul Railway trains from Chicago to Kansas City also pass through Fairport, using the Rock Island tracks.

The Fairport station was established by Act of Congress for mussel propagation and biological investigations. It has been in construction for several years, during which period the permanent staff of the station and a few associates have been engaged, apart from the propagation work, in experiments and other forms of investigation, both at the station and in the field in various parts of the Mississippi basin. Small temporary quarters were occupied.

The permanent laboratory building, which is about 50 × 100 feet, was constructed last year, and it is now largely equipped and ready for summer occupancy. The two main stories of the laboratory building comprise a general laboratory, and several smaller special laboratories, a library, storeroom, offices and six bed-chambers. On the third floor are additional bed-chambers and storage compartments, while the dining-room and kitchen are located in the basement. The building is supplied throughout with filtered water from an underground concrete cistern on the hillside.

On the grounds below and above the railway are ten earth ponds, the largest of which is an acre and a quarter in extent, and fourteen small concrete-lined ponds of different forms and depth. There is also a tank house, twenty-five by fifty feet, in which are various tanks and troughs. The ponds and the tank house are supplied with unfiltered river water drawn by gravity from a storage basin holding about two million gallons. The pumping equipment consists of three steam-turbine-driven pumping units of a maximum pumping

capacity of about three million gallons per day. An artesian well on the grounds near the river offers a limited flow of hard water, which is not stored.

The grounds comprise sixty acres of cleared and wooded land, mostly with a gentle slope, and extending from the banks of the river to the top of the bluffs. The river frontage is about a quarter of a mile.

The station has two launches and a number of rowboats, with one portable Evinrude motor. A fishing crew is engaged almost daily. Opportunities are, therefore, offered for collecting in the various parts of the river or in the lakes and slues which are found in the islands and the lowlands of the Illinois shore. Interesting aquatic environments are also presented by the ponds on the station grounds, which are generally very rich in plankton.

The laboratory will not only be used by the permanent staff and associates of the bureau engaged on special problems, but it is desired to extend the facilities of the institution to other investigators desiring to study problems for which the conditions at Fairport may be particularly favorable.

The laboratory is furnished with the ordinary glassware and scientific apparatus. No charge will be made for occupancy of tables or dormitory rooms, but the mess will be operated upon a cooperative plan, each participant sharing in the expense. Further conditions and information will be supplied upon request.

Since only a limited number can be accommodated in the first season, it is requested that applicants for tables address the Commissioner of Fisheries, Washington, D. C., or the director of the biological station, Fairport, Iowa, as early as practicable. Investigators requiring the use of special or unusual apparatus should communicate particularly with the director, in order that they may be informed as to the special equipment of the station related to their needs.

ROBERT E. COKER,
Director

March 2, 1914

A NATIONAL ASSOCIATION OF UNIVERSITY PROFESSORS

IN the spring of 1913 a circular letter, signed by most of the full professors of the Johns Hopkins University, was sent to members of the faculties of nine other universities, inviting them to consider the advisability of the formation of a national association of university professors, and to send delegates to an informal conference for the discussion of the matter. The letter contained the following statement of the reasons actuating the signers of it:

The reasons which seem to demand the formation of such an association are fairly evident. The university teacher is professionally concerned with two distinct, though related, interests. Both of these interests can be furthered by cooperation and the interchange of views, and therefore, by organization; for only one of them has suitable organization yet been attained. As scholar and investigator the teacher is interested in the advancement of learning and the diffusion of knowledge in his specialty; and cooperative effort for these ends is already effectively organized, through our numerous technical societies and the several sections of the American Association. But the university professor is also concerned, as a member of the legislative body of his local institution, with many questions of educational policy which are of more than local significance; he is a member of a professional body which is the special custodian of certain ideals, and the organ for the performance of certain functions essential to the well-being of society; and concerning the character, efficiency, public influence and good repute of this body he can not be indifferent. It is on this side that there is need for more definite and more comprehensive organization. The general purposes, therefore, of the contemplated association would be to promote a more general and methodical discussion of the educational problems of the university; to create means for the authoritative expression of the public opinion of the profession; and to make possible collective action, on occasions when such action seems called for.

A favorable response was received in all cases, and statements expressing the belief in the desirability of the formation of such an association were drawn up and signed by members of the faculties of most of the uni-

versities addressed. The proposed conference was held in Baltimore on November 17, 1913, on the eve of the annual meeting of the National Academy of Sciences. It was attended by eighteen delegates, from the following universities: Clark (Professors Taber and Webster); Columbia (Professors Cattell and Dewey); Cornell (Professors Bennett and Nichols); Harvard (Professor Minot); Johns Hopkins (Professors Ames, Bloomfield, Lovejoy, Morley); Princeton (Professors Capps, Kemmerer, Warren); Wisconsin (Professors Cole, Marlatt), and Yale (Professors Harrison, Mendel). After prolonged discussion of the whole subject it was unanimously voted that the organization of the proposed association should be undertaken; and the chairman, Professor Bloomfield, was authorized to appoint a committee, representing the principal subjects of study and the principal universities, (a) to determine what professors, or classes of professors, should be invited to attend a meeting, to be held at some time during the current year, for the formal establishment of the association; (b) to determine the time and place of this meeting, and (c) to prepare a draft of a constitution. After some unavoidable delays, the chairman of the conference has announced the composition of the committee as follows: Astronomy, George C. Comstock (Wis.); Biological Sciences, E. G. Conklin (Princeton), R. G. Harrison (Yale) and Theodore Hough (Virginia); Classical Philology, E. Capps (Princeton); Chemistry, Julius Stieglitz (Chicago); Economics, M. A. Aldrich (Tulane), Alvin S. Johnson (Cornell); Education and Psychology, John Dewey (Columbia); Engineering, Guido Marx (Stanford); English, J. W. Bright (Johns Hopkins), C. M. Gayley (California); Geology, W. H. Hobbs (Mich.); Germanic Philology, M. G. Learned (Penn.); History, W. E. Dodd (Chicago); Law, Roscoe Pound (Harvard); Mathematics, C. J. Keyser (Columbia), Henry Taber (Clark); Medicine, C. S. Minot (Harvard); Oriental Languages, Morris Jastrow (Penn.); Philosophy, A. O. Lovejoy (Johns Hopkins), Frank Thilly (Cornell); Physics, C. E. Mendenhall (Wis.); Political Science,

Isidor Loeb (Missouri); Romance Philology, F. M. Warren (Yale). Professor Dewey has consented to act as chairman.

In selecting the members of this committee of twenty-five, the chairman of the conference has, of course, had in mind three criteria: the representation of the principal universities, the representation of the several sciences, and the special qualifications of individuals for service upon such a committee. With very few exceptions those first asked to serve upon the committee have readily agreed to do so. In two or three instances, however, it has been necessary to leave important universities thus far unrepresented, owing to the inability of the professors first invited to serve, and the inexpediency of further delaying public announcement of the committee's membership until other representatives of those institutions could be selected and notified, and their acceptances be received. The committee may be expected to begin at once the consideration of the questions submitted to it; and it will doubtless be able to announce the date of the contemplated meeting, and its general proposals with respect to the association, within a few months.

SCIENTIFIC NOTES AND NEWS

THE College of Physicians of Philadelphia, the American Philosophical Society, the Library Company of Philadelphia, the Jefferson Medical College and the Academy of Natural Sciences have arranged a memorial in honor of the late Dr. S. Weir Mitchell, to be held on the evening of March 31, in the Hall of the College of Physicians. Addresses will be delivered by Dr. Talcott Williams, New York City; Dr. William H. Welch, Baltimore, and Mr. Owen Wister, Philadelphia.

DR. CHARLES W. ELIOT, president emeritus of Harvard University, celebrated his eightieth birthday on March 20.

A PORTRAIT of Dr. James Ward, professor of mental philosophy at the University of Cambridge, by Mr. Ambrose McEvoy, has been presented to the university.

THE University of Cambridge proposes to confer on the occasion of the opening of the new physiological laboratory on June 9 the degree of doctor of science on Sir William Osler, Sir David Ferrier, Sir E. A. Schäfer and Professor E. H. Starling.

THE opening ceremonies of the Institute for Medical Research, founded with an endowment of \$1,000,000 by Mrs. George William Hooper in memory of her husband, were held on March 7 at the University of California Hospital, San Francisco. Addresses were made by Dr. Henry S. Pritchett, of the Carnegie Foundation, on "The Value of Medical Research to a Great City," and by Dr. Richard Mills Pearce, Philadelphia, on "The Opportunity of the University in Medical Research."

THE Vienna Prehistoric Society was recently founded with Professor Moritz Hoernes, of the University of Vienna, as its president.

ON the occasion of the thirtieth anniversary of the *Circolo Matematico* of Palermo a gold medal will be presented to Dr. Giovanni B. Guccia, founder of the society and editor of its publications.

THE Hon. Bertrand Russell, of the University of Cambridge, has taken up his duties at Harvard University during the second half-year.

PROFESSOR CHARLES E. BESSEY, of the University of Nebraska, is spending the month of March at the Desert Botanical Laboratory of the Carnegie Institution near Tucson, Arizona. Professor Bessey plans to study and collect material of numerous species of the desert flora. While he is away Dr. R. J. Pool is in charge of the department of botany at the University of Nebraska.

PROFESSOR WILLIAM T. SEDGWICK, head of the department of biology and public health at the Massachusetts Institute of Technology, has been given leave of absence for the present term, on account of a recent illness. He will pass the time in southern Europe.

MR. FRANK ALVORD PERRETT, the American volcanologist, has been slightly burned on the hands and legs by an explosion of molten lava while studying the volcano of Sakura-Jima.

A TESTIMONIAL dinner was tendered to Dr. Samuel Sheldon at the Hotel Astor on March 21 to celebrate a quarter of a century of service as professor at the Polytechnic Institute of Brooklyn.

THE members of the Chemists' Club, New York, gave a complimentary dinner to Dr. Wolfgang Ostwald, of the University of Leipzig, on March 19.

MR. EMIL HUBER-STOCKAR, engineer in charge for the Swiss government of the electrification of the Gothard tunnel and president of the Swiss national committee of the International Electrotechnical Commission, was a guest of honor at a dinner given at the Engineers' Club, New York City, on March 13, by Mr. C. O. Mailloux, president of the American Institute of Electrical Engineers.

PROFESSOR GEORGE GRANT MACCURDY, of Yale University, has been elected a corresponding member of the Numismatic and Antiquarian Society of Philadelphia.

MR. FRANÇOIS E. MATTHES, associate geologist of the U. S. Geological Survey, has been elected a corresponding member of the International Glacier Commission.

PROFESSOR H. H. NORRIS, until last year professor of electrical engineering in Cornell University, has accepted an appointment as associate editor of the *Electric Railway Journal*, and, beginning on July 1, when his term as secretary of the Society for the Promotion of Engineering Education expires, he will devote his entire time to that publication.

CARL SPENCER MILLIKEN has been appointed assistant superintendent of Agricultural Extension in the University of California, with headquarters at the Graduate School of Tropical Agriculture at Riverside.

DR. HENRY NORRIS RUSSELL, professor of astronomy in Princeton University, lectured before the Columbia Chapter of Sigma Xi on March 24, the subject being "Eclipsing Variable Stars."

PROFESSOR ROSWELL H. JOHNSON, of the University of Pittsburgh, lectured before the department of geology of Columbia Univer-

sity on March 24 and 26, the subjects of his lectures being "The Origin of Petroleum and Natural Gas, New and Old Theories" and "Proposed Methods of Securing an Increased Yield from Oil-wells."

PROFESSOR ARTHUR W. GOODSPEED, of the University of Pennsylvania, lectured at Bucknell University on March 13 on "Radioactivity with Special Reference to Radium."

PROFESSOR F. E. LLOYD, of McGill University, recently gave a lecture before the Ottawa Field Naturalist's Club on the subject of "Abscession in Flowers, Fruits and Leaves."

PROFESSOR GEORGE GRANT MACCURDY, of Yale University, completed on March 10 a tour of the eastern Canadian circuit, where he lectured on "The Dawn of Art" by invitation of the Archeological Institute of America at St. John, Halifax, Quebec, Montreal, Ottawa, Toronto and Hamilton.

ADOLPH FRANCIS ALPHONSE BANDELIER, a distinguished authority on South American archeology, lecturer in Columbia University, died in Madrid, Spain, on March 20, aged seventy-four years.

DR. W. T. DUTTON, professor of mathematics and civil engineering at Allegheny College, in Meadville, Pa., has died at the age of sixty-two years.

PROFESSOR GIUSEPPE MERCALLI, director of the Mount Vesuvius observatory, and professor of vulcanology and seismology in the University of Naples, has died at the age of sixty-four years, having been burned by the overturning of a lamp, or perhaps murdered.

DR. EDWARD C. PICKERING, director of the Harvard College Observatory, has sent under date of March 10, the following bulletin:

The following statement has been received from Professor W. H. Pickering, in charge of the Mandeville Station of this observatory: Attention was called to the lunar crater, Einmart, in A. N. 4704. It is there stated that its interior was very brilliant in January, 1913, but since March had been very much darker. This darkness persisted throughout the remainder of the year, and through January of this year. In February, however, it again brightened up, being about as bright as it

was in February, 1913, though by no means as brilliant as in January of that year. As it is a large crater, 25 miles in diameter, the brightness of its interior may be easily observed, even with a small telescope and under unfavorable atmospheric conditions. This past month it has been clearly brighter than any area of similar size between it and the limb. This had not been the case since the previous March. In the preceding January it was the brightest area of that size visible at that time upon the Moon. All observations should be made immediately following the first quarter. The interior is full of fine brilliant detail, constantly varying, not only from night to night, but also from month to month. This observation is, however, probably too difficult for any northern telescope, since it requires not merely one, but a succession of fine nights.

THERE is in the Paris Museum of Natural History a skull, which, according to tradition, once enclosed the brain of Descartes. The *British Medical Journal* says that the Academy of Fine Arts recently invited Dr. Paul Richer, professor of anatomy in the Paris School of Fine Arts, and a member both of the Academy of Medicine and the Academy of Fine Arts, to compare by scientific methods, in collaboration with M. Gaston Darboux, the supposed skull of Descartes with the different portraits of the famous philosopher. Dr. Richer indicated on a plaster cast given him by the museum certain distinctive characters which are well marked on the head of the portrait painted by Franz Hals. It is said to be on these resemblances that Cuvier based the opinion that the skull is authentic, which he expressed in 1821. He next drew a skull, as closely adapted as possible, resembling that outlined in the portrait. Then he made a drawing of the museum skull posed with the same orientation and on the same scale as the head of the portrait. Lastly, he superimposed the two drawings. In his first drawing Dr. Richer marked certain points—at the root of the bones of the nose, on the external orbital apophyses, and on the nasal spine. These same points were repeated on the cast of the skull in the museum. By means of these marks it was easy to place with almost mathematical precision the skull in the posi-

tion which Hals had given his model. The superimposition of the two drawings showed an almost absolute agreement. On the other hand, other drawings made under the same conditions of several skulls taken at random, showed notable discrepancies. The same experiment was repeated with the other portraits of Descartes, namely, that by Sebastian Bourdon in the Louvre; that of Beck, of which there is a copy in the library of the institute, the terra cotta medallion of the Versailles Museum, and an old portrait by an unknown painter belonging to M. Rulhe, of Courvevoie. The comparison of the skulls in these different portraits with that of the museum shows some striking resemblances, but never so complete an agreement as was found with the Hals portrait. Before Dr. Richer began his investigation much the same procedure was employed by Dr. Verneau, professor of anthropology at the museum, who came to the same conclusion. As a matter of history it is known that the skull was detached from the philosopher's body in 1666 by Israel Planstrom, Captain of the Queen of Sweden's Guards, and it was given to the French nation by Berzelius. Now that the relic has been satisfactorily identified, it is suggested that it should be placed in the coffin which contains the decapitated skeleton of the philosopher. This is in the Church of Saint Germain des Prés, where it lies in one of the chapels between the remains of Mabilion and those of Montfaucon. Another suggestion is that the skeleton and skull might be solemnly transferred to the Pantheon in accordance with a decree of the Convention of October 2, 1793, to which effect was never given. At a meeting of the Académie des Sciences on January 20, Professor Edmond Perrier declared that the identification having been made conclusively, it was no longer right that this relic of the great thinker should be left amidst the collections of the gallery of anthropology and paleontology in the museum. He undertook to have a kind of reliquary constructed in one of the rooms of the museum where there are already relics of other famous men. There the skull of Descartes will be

deposited, together with the documents establishing its authenticity.

UNIVERSITY AND EDUCATIONAL NEWS

TENTATIVE plans for buildings to replace the burned College Hall of Wellesley College provide for a quadrangle, including four buildings, on the old site. It is expected that the college will be able to reopen on April 7.

AMHERST COLLEGE has received a bequest of \$5,000 for a scholarship under the will of Addison Brown, late of New York, and a non-graduate of the class of 1852.

UNDER the will of the late Dr. Rosewell Park the medical department of the University of Buffalo will receive his entire medical library of about three thousand volumes.

THE valuable psychological library of Dr. Arthur Henry Pierce, late professor of psychology at Smith College, has been given to the college.

It is said that the secretary of the interior has written to the chairman of the house committee on education expressing disapproval of the bill to establish a national university.

THE first structure that the Massachusetts Institute of Technology has erected for its own uses on its site in Cambridge is the new aerodynamic laboratory. The building is finished and the apparatus is in process of installation. The portion of its equipment that is first to be installed is the four-foot wind tunnel with its accompanying blower. This is of the pattern now in use at the National Physical Laboratory at Teddington, England, which has furnished the plans.

It is expected that a school of fisheries will be established at the University of Washington. If the plans mature, the resulting school will be the first school of its kind in the United States, though there are such schools in Japan and other countries.

PROFESSOR FREDERICK SLOCUM, who for the past four years has been in charge of the solar observations and stellar parallax work at the Yerkes Observatory, has been elected professor

of astronomy at Wesleyan University, Middletown, Conn., and will assume his new duties in the autumn. A new observatory will be erected immediately as a memorial to the late Professor Van Vleck, for many years in charge of that department at Wesleyan.

DR. WILLIAM C. ALPERS, formerly a trustee of the College of Pharmacy of Columbia University, has been appointed dean and professor of pharmacy of the pharmaceutical department of Western Reserve University.

MR. ROBERT N. HOYT, '09, has been appointed by the corporation of the Massachusetts Institute of Technology special lecturer on public health administration.

MR. SEARCY B. SLACK, B.S., Georgia, '11; A.M., Harvard, '12, has been appointed adjunct professor of civil engineering and road expert at the University of Georgia.

PROFESSOR BURTON H. CAMP, who has been associate professor of mathematics at Wesleyan University, has been advanced to a full professorship.

DR. ELLIS M. FROST, instructor in clinical medicine and microscopic anatomy in the School of Medicine, University of Pittsburgh, has been appointed to the position of director of the department of health of the university.

DISCUSSION AND CORRESPONDENCE

SMALL AERIALS AND THE STRENGTH OF WIRELESS SIGNALS

FEW persons realize the ease with which wireless signals, such as are sent from the Navy station at Arlington, Va., and Sayville, Long Island, may be intercepted and read, even when one is some distance from the sending station.

In connection with some experiments on the effect of foliage, humidity, etc., on the strength of the wireless signals sent from the government station at Arlington, the writer was impressed by the large amount of power intercepted by an aerial erected on the university campus and an attempt was made to see if these signals could be read with a much less pretentious aerial. During the writer's

summer vacation spent near Morgantown, W. Va., on the banks of the Monongahela River, a T aerial consisting of two No. 18 wires, 100 feet long, was stretched up between two trees on the side of a hill at the back of the camp. This aerial was approximately 30 feet high and 50 feet from the top of the hill. There were quite a few trees in the neighborhood of the aerial and in most cases they extended well above the highest point of the aerial. Some difficulty was met with in trying to find a satisfactory ground connection, but as soon as that was secured the "time signals" could be heard very clearly even in the brightest sunshine and on the warmest days of last August.

Upon the writer's return to Morgantown he found that not only the "time signals" from Arlington but the Sayville Long Island press dispatches could be heard with a T aerial consisting of three No. 18 wires, 30 feet long, fastened to the rafters in the attic of his residence. Later experiments showed that both these signals could not only be heard, but were loud enough to be read by using an ordinary iron bed with a wire soldered to the middle of one side for the aerial. The bed was located on the second floor of the house and was about 12 feet above the level of the street.

The receiving apparatus consisted of a Navy type of loose-coupled receiving transformer, a variable condenser, a silicon detector used without batteries and 1,000-ohm telephone receivers. A gas pipe leading to a gas stove in the room served as the ground line.

Morgantown is 162.3 miles from Arlington, Va., and 374.6 miles from Sayville, Long Island, with both the Blue Ridge and the Allegheny Mountains between. The peaks of some of these mountains rise as high as 2,200 feet above the top of the writer's residence and for the most part are covered with forests. In view of the distance from the sending stations and the mountainous character of the country over which these signals are transmitted the results obtained with these low and small aerials seem to warrant this brief description.

C. W. WAGGONER

WEST VIRGINIA UNIVERSITY,
MORGANTOWN, WEST VIRGINIA

A SIMPLE APPARATUS FOR WASHING SMALL AND DELICATE OBJECTS FOR SECTIONING

THE apparatus here described was devised for washing small and delicate objects fixed in Flemming-fluid. It has been found successful and economical for washing with distilled water also.

The apparatus consists of a *round-bottomed* glass tube, six inches long and one inch in diameter, a double-bored, tightly fitting stop-

per,¹ through which the inlet tube *A* and the U-shaped outlet tube *B* pass.

The inlet tube *A* should be inserted at a slight angle so that its lower end lies in the center of the round-bottomed tube within half an inch of the bottom. This end is covered with a piece of fine bolting-silk fastened with a rubber band. The bolting-silk breaks the force of the inflowing water, but more especially prevents the entrance of any foreign substance which might close the outlet. The upper end of tube *A* is connected by a rubber tube to the distilled water reservoir or faucet. The flow of water is regulated by screw compressor *C*.

The outlet tube *B* has its inner arm a trifle longer than the outer arm, so that the U does

¹ The stopper and small tubes must fit tightly to maintain an air chamber between the stopper and the lower end of tube *B*.

not act as a syphon. The inner arm of this tube is covered with bolting-silk also, to prevent the escape of any material which may float.²

With the water merely dripping, a liter per hour, the material is kept in constant motion and thoroughly washed.

S. I. KORNHAUSER

THE CORRESPONDENCE OF LINNAEUS

TO THE EDITOR OF SCIENCE: Dr. J. M. Hulth, of the University Library of Upsala, who has succeeded to the editorship of Carl von Linné's correspondence, formerly edited by the late Professor Th. M. Fries, desires information as to the whereabouts of letters to and from Linné which might be found in collections in this country. Individuals or institutions having such letters are asked to communicate with the undersigned.

AKSEL G. S. JOSEPHSON

THE JOHN CREER LIBRARY,
CHICAGO, ILL.

EXHIBITION OF THE ROYAL PHOTOGRAPHIC SOCIETY

TO THE EDITOR OF SCIENCE: The Royal Photographic Society of Great Britain are holding their fifty-ninth annual exhibition in August and September of this year. This is the most representative exhibition of photographic work in the world, and the society is anxious to make it more international in character. It is very desirable that American scientific photography should be fully represented at the exhibition, and in order to enable this to be done with less work to the exhibitor, I have arranged to collect and forward American work intended for the scientific section.

This work should consist of prints showing the use of photography for scientific purposes and its application to spectroscopy, astronomy, radiography, biology, etc. Photographs should reach me not later than Friday, July 10. They should be mounted but not framed.

² If the objects to be washed tend to float, a disk of perforated celluloid through which the inlet tube passes may be placed about an inch from the bottom of the larger tube.

I should be glad if any worker who is able to send photographs will communicate with me as soon as possible so that I might arrange for the receiving and entry of the exhibit.

SCIENTIFIC BOOKS

Definitions in Physics. By KARL EUGEN GUTHE, Ph.D., Professor of Physics in the University of Michigan and Dean of the Graduate Department. New York, The Macmillan Company. 1913. Pp. vii + 107.

A man's convictions are vastly more important than the logical processes by which he reaches them; and his convictions are represented in a large degree by the definitions which he adopts. It follows, therefore, that the appearance of a volume of definitions by a scholar of high standing in any particular field of thought is a matter of some moment. There is danger of taking physics too seriously; and nothing is easier than to employ definitions in such a way as to produce in the student-mind what Professor Franklin calls "a stress of dryness." But when the technical terms of his own science have been collected by a well-known specialist they become a matter of keen interest, and all the more so when that specialist is an experienced and successful teacher as is Professor Guthe.

Definitions grow as our ideas grow. They are not the fixtures of the Medes and Persians. Compare the modern definition of the crab with the classical one given in the French Academy's dictionary. Or consider how the resistance term in Ohm's law developed into impedance upon the introduction of alternating currents. Previous to the renaissance forces were defined only in a statical way; anything that would flatten out the muscles of the hand, bend a beam, disturb the configuration of a steelyard, or bring out any other strain requiring work was classified as a *force*; and conversely the term *force* was used at that

time to include many ideas, such as *speed*, *impulse*, *energy* and *power*, which now lie quite without its limits. Shortly after the renaissance the concept of force was enlarged so as to take in the time-rate of change of momentum; later the generalized forces of Lagrange are included. Again the Peltier effect is defined quite differently from what it was before the Thomson effect was discovered.

A list of definitions is therefore a list of variable quantities and can hardly be regarded as more than a cross-section of the conventions agreed upon by the generation which uses them.

The book under review is one which can not fail to be of the utmost help to any student of general physics. The definitions are arranged under the classical five chapters of physics. Each quantitative concept is, as a rule, first defined in simple English and in terms already explained or assumed; next follows a mathematical expression which may be considered as a repetition of the first definition, and frequently, as an expression of natural law. The definitions are remarkable for their clearness, simplicity and brevity; if at any point indefiniteness suggests itself one feels that additional details have been omitted only to secure brevity. This feature is illustrated by the first paragraph in the book which defines *physics* in a manner which is elegant but so general as to leave doubt in the reader's mind as to whether physics and physical science are one and the same.

At the outset the author enunciates his conviction that "certain concepts used in physics are deductions and generalizations from individual experience and can not be strictly defined. Such are the concepts of *extension* (space, with its subdivisions of volume, area, length and direction), *time*, *force*, *warmth*, *cold*, etc." On the same page, a *physical quantity* is defined as "a definite concept capable of measurement."

Every one who thus finds *force* listed among the indefinables will surely understand that Professor Guthe here means to imply nothing more than that no complete and satisfactory definition has yet been given. For only a few

pages later we find that he himself offers the following definition:

"Force is the cause of a change or of a tendency to change in the state of rest of a body or of its deviation from uniform rectilinear motion. The idea of force is based upon the fundamental concept of the effort necessary to change the position of a body at rest or the uniform rectilinear motion of a body. It is assumed to be the cause of such a change, to be proportional to the acceleration produced, and to be in the direction of the added acceleration. It is a vector quantity. A force is measured by the equation $F=ma$, which may serve as a definition."

Waiving all considerations which might be urged against this definition on the ground that physics is not at all concerned with "causes," and laying aside all pedagogical considerations, your reviewer would like to ask, purely for information, this one question: Is there any single property, save only the space-variation of energy, which is characteristic of all the physical quantities which one finds labelled as "forces" by the leading physicists of the present time? Is there any single feature, or set of features, which can serve as a defining quality for force? No question is here raised about any general definition of force such as that which occupies ten columns of fine print in the great Oxford Dictionary. *The inquiry here made is much simpler. It pertains only to the forces which are employed every day in physics.* The one and serious objection against defining force in terms of energy or work is, of course, the fact that work and energy are universally defined in terms of force.

The crux of the situation would then appear to be the following: one is compelled either to employ the vicious circle just indicated or to discover some property other than space-variation of energy, which is common to all forces. It goes without saying, perhaps, that the space-variation here referred to is that employed by Lagrange in his definition of generalized force,¹ and is intended to include both angular and linear space. To make it perfectly

¹ *Mec. Anal.*, I., p. 334.

clear that there is nothing hazy or indefinite about the query here raised it may be well to summarize the principal types of force which one meets in any standard discussion, such as that of Thomson and Tait, or Webster.

1. First of all there is the straightaway mass-acceleration in which the momentum of a particle is altered while its direction of motion remains constant, *e. g.*, a particle falling under gravity.

2. The force which produces a change in the direction of momentum of a particle, leaving the scalar value of its momentum constant, *e. g.*, centrifugal force, *mvo*.

3. The non-conservative force which is independent of the speed and is illustrated, within limits, by that of sliding friction. One may of course assign a part of the force of friction to the mass-acceleration of the small abraded particles.

4. The non-conservative force which varies directly as the speed, and possesses a dissipation function, illustrated by certain viscous resistances. Here again one may assign acceleration, hence speed and heat, to the small invisible particles.

5. The force which produces a change in the shape or size of an elastic body or in the configuration of a gravitational, magnetic or electric system.

The reader will find a more elegant analysis of the typical mechanical forces in Webster's "Dynamics," p. 123; but the above list suffices to show the diversity in which some common factor is sought. If we admit that a mass-acceleration is characteristic of the first four types listed above, can the all-powerful electron theory bring the fifth type also into this category? Or is there some better way around this *impasse*? Or must we concur with Professor Guthe in his opinion that force can not be defined? To say that it is sometimes definable and sometimes not is about as satisfactory as that ancient testimonial of good character which asserted that "the man is honest; at least he is honest nine times out of ten." Even those who believe there is something profound and mysterious about the concept of force, just as there is something

away beyond our ken in the structure of matter, say of copper, will confess that the chemist can point to a certain set of properties which are necessary and sufficient to delimit copper from every other known substance. The question here raised is similar, namely, Can forces be grouped into a class by themselves? And, if so, what are the marks, or the one mark, by which this class is set off from the other physical quantities? Dr. Dadourian, in his "Analytical Mechanics," p. 15, has perhaps given an answer to this question: but if so, only by introducing a term—*action*—which the intelligent reader will consider an undefined synonym of *force*, equally complex and equally indefinite.² Every one agrees that a force is represented, in a general way, by a *push* or *pull*; but the question here raised is this: How is a *push* to be defined in a quantitative and consistent manner?

Returning now from this digression suggested by Professor Guthe's treatment of mechanics, the definitions in *Sound* and *Heat* are brief and excellent. Those in Magnetism and Electricity are introduced with the interesting remark that "the existence of ether in space is accepted as a means of interpreting phenomena that can not be explained by the properties of ordinary matter." The definitions which follow are especially fine and are certain to furnish new and helpful viewpoints to any serious student; the same is true of the section devoted to optics. Where differences of opinion might arise—and they are numerous—one feels always that the text, as it stands, clearly sets forth the essential facts of the case.

HENRY CREW

Introduction to the Study of Igneous Rocks.

By GEORGE I. FINLAY, Ph.D. New York and London. McGraw-Hill Book Company, Inc. 1913. Pp. vii + 228. Price \$2.00 net.

This little book is said by its author to be intended as an introduction to the exhaustive treatises on the subject of igneous rocks, and consists of a brief statement of the qualitative classification of igneous rocks; a description

of the method of determining such rocks in hand specimens, and a short chapter on the optical properties of minerals and the methods by which they are determined. This is followed by chapters on identification of the essential and accessory minerals of igneous rocks; and by chapters on the "igneous type rocks" and of varietal rocks related to the type rocks; a brief synopsis of a method of describing rocks; and an outline of the quantitative classification of igneous rocks, with numerous examples of the method of calculation of the norm, with numerical tables to facilitate the calculation. There are also tabulated statements of the physical characteristics of the chief rock minerals.

The book is well gotten up and is to be commended for its author's appreciation of the value of quantitative methods of determination and description, and for his simple and direct manner of describing the ordinary method of procedure in the customary identification of rocks in hand specimens, and of minerals under the microscope.

It is a mistake, however, to call the book an introduction to the more serious study of igneous rocks as set forth in larger treatises on the subject. It would seem to have been prepared for a class of students who did not intend to study the subject thoroughly, a very large and legitimate class who desire only a slight knowledge of the subject. For the work labors under the disadvantage of an attempt to simplify a highly complex subject, and to express in a few words ideas and definitions which require fuller statements and amplification in order to be correct. The attempt has led the author into some errors that he might have avoided. It has emphasized the idea of rock types, which will lead students to expect what they will not find in nature, and it has given false ideas as to the composition of rocks having the commonest names. The author himself remarks that the concise statement made in the table of igneous rocks on page 98 may readily be misinterpreted by the beginner. Why then make it? It certainly conveys the impression that andesites are characterized by mica and amphibole, and that

² See Rettger, *SCIENCE*, January 23, 1914, p. 140.

pyroxene is subordinate. One who is not a beginner knows that most andesites contain more pyroxene than mica or amphibole; and in many instances pyroxene without either mica or amphibole. The impression is also given that granite does not contain lime-soda-feldspar. There are numerous inaccuracies of statement and definition that might be pointed out, which may be charged to the attempt at simplification. It does not seem desirable that students who intend studying petrology thoroughly should begin by studying it in an inadequate manner, and experience the necessity of remodeling some of their fundamental concepts.

JOSEPH P. IDINGS

An Introduction to the History of Medicine, with Medical Chronology, Bibliographic Data and Test Questions. By FIELDING H. GARRISON, A.B., M.D. Philadelphia, W. B. Saunders Co. 1913.

The reproach that has been brought against modern science to the effect that it looks only to the present and future and gives little consideration to the past, probably finds the least amount of justification in the case of the medical sciences, if one may judge from the rapid increase within recent years in the amount of literature, both periodical and monographic, that deals with the history of these sciences. But it has been to France, and more especially to Germany, that we have been principally indebted for compendious treatises on the history of medicine, the only works of that nature written within recent years by English-speaking authors being the brief "Epitome" of Dr. Roswell Park and the delightful "History of Physiology" by Sir Michael Foster. The publication of the work before us is, therefore, an event of no little interest, since it places in the hands of English readers a reliable, comprehensive and interesting account of the development of medical theory and practise, from the earliest times down even to the present day. It is noteworthy also in that its production has been made possible by the unequalled collection of works dealing with the history of medicine that has been brought to-

gether in the library of the surgeon-general at Washington. Dr. Garrison is to be heartily congratulated upon the excellent use he has made of it.

The book opens with an introductory chapter on the identity of all forms of ancient and primitive medicine, and then follow chapters on Egyptian, Sumerian and Oriental, Greek (under which are included the Alexandrian and Roman schools), Byzantine, Mohammedan and Jewish, and medieval medicine, all these being treated in the brief space of one hundred and thirty pages. Then follows a well-balanced chapter on the period of the Renaissance, but the greater part of the book, nearly five hundred pages out of six hundred and sixty odd, is devoted to the history of the sixteenth to the twentieth centuries, the chapter on the twentieth century giving a welcome review of the development of our knowledge of such subjects as the internal secretions, the synthesis of proteins, parasitology, chemo- and sero-therapy.

Each chapter consists of a biographic and a general portion, the former setting forth the main features of the lives, endeavors and accomplishments of those who have contributed in any degree to the advancement of medicine, while the latter sums up succinctly and clearly the conditions under which they lived and worked. As appendices there are added a useful medical chronology, a bibliography and a number of test questions, many of which suggest interesting topics for further study and investigation. Finally, mention should be made of the excellent indexes, one of persons and another of subjects, both of which appear to be entirely satisfactory.

Dr. Garrison's book forms a trustworthy reference for those who are interested in any phase of the development of medicine. No name worthy of mention, unless it be that of Dodoens, seems to have been omitted, and although the treatment is fundamentally biographic, the subject index makes it easy to ascertain the essential events in the development of special departments of medicine. And yet with all this thoroughness in so small

a compass, the book is far from being a mere catalogue of names, facts and dates. The author's style gives life to his descriptions; he has the happy faculty of seizing upon the salient points of his subject and vivifying them by allusion, comparison and quotation. Interest, too, in the text is greatly increased by the large number of portraits with which it is illustrated, a feature that especially distinguishes the book in comparison with its predecessors.
